Paola Grosso,

Bert Andree, Karst Koymans, Cees de Laat

Fernando Kuipers (TU Delft)

This work is funded by the Gigaport Project

dinsdag 18 september 2007

Multi-layer path finding is a problem. I will not give an answer to that, but I will show that there is a problem, and give you both an information and a data model to use.

This is an Example

For the actual network, ask your NREN
(That may be the person sitting next to you)

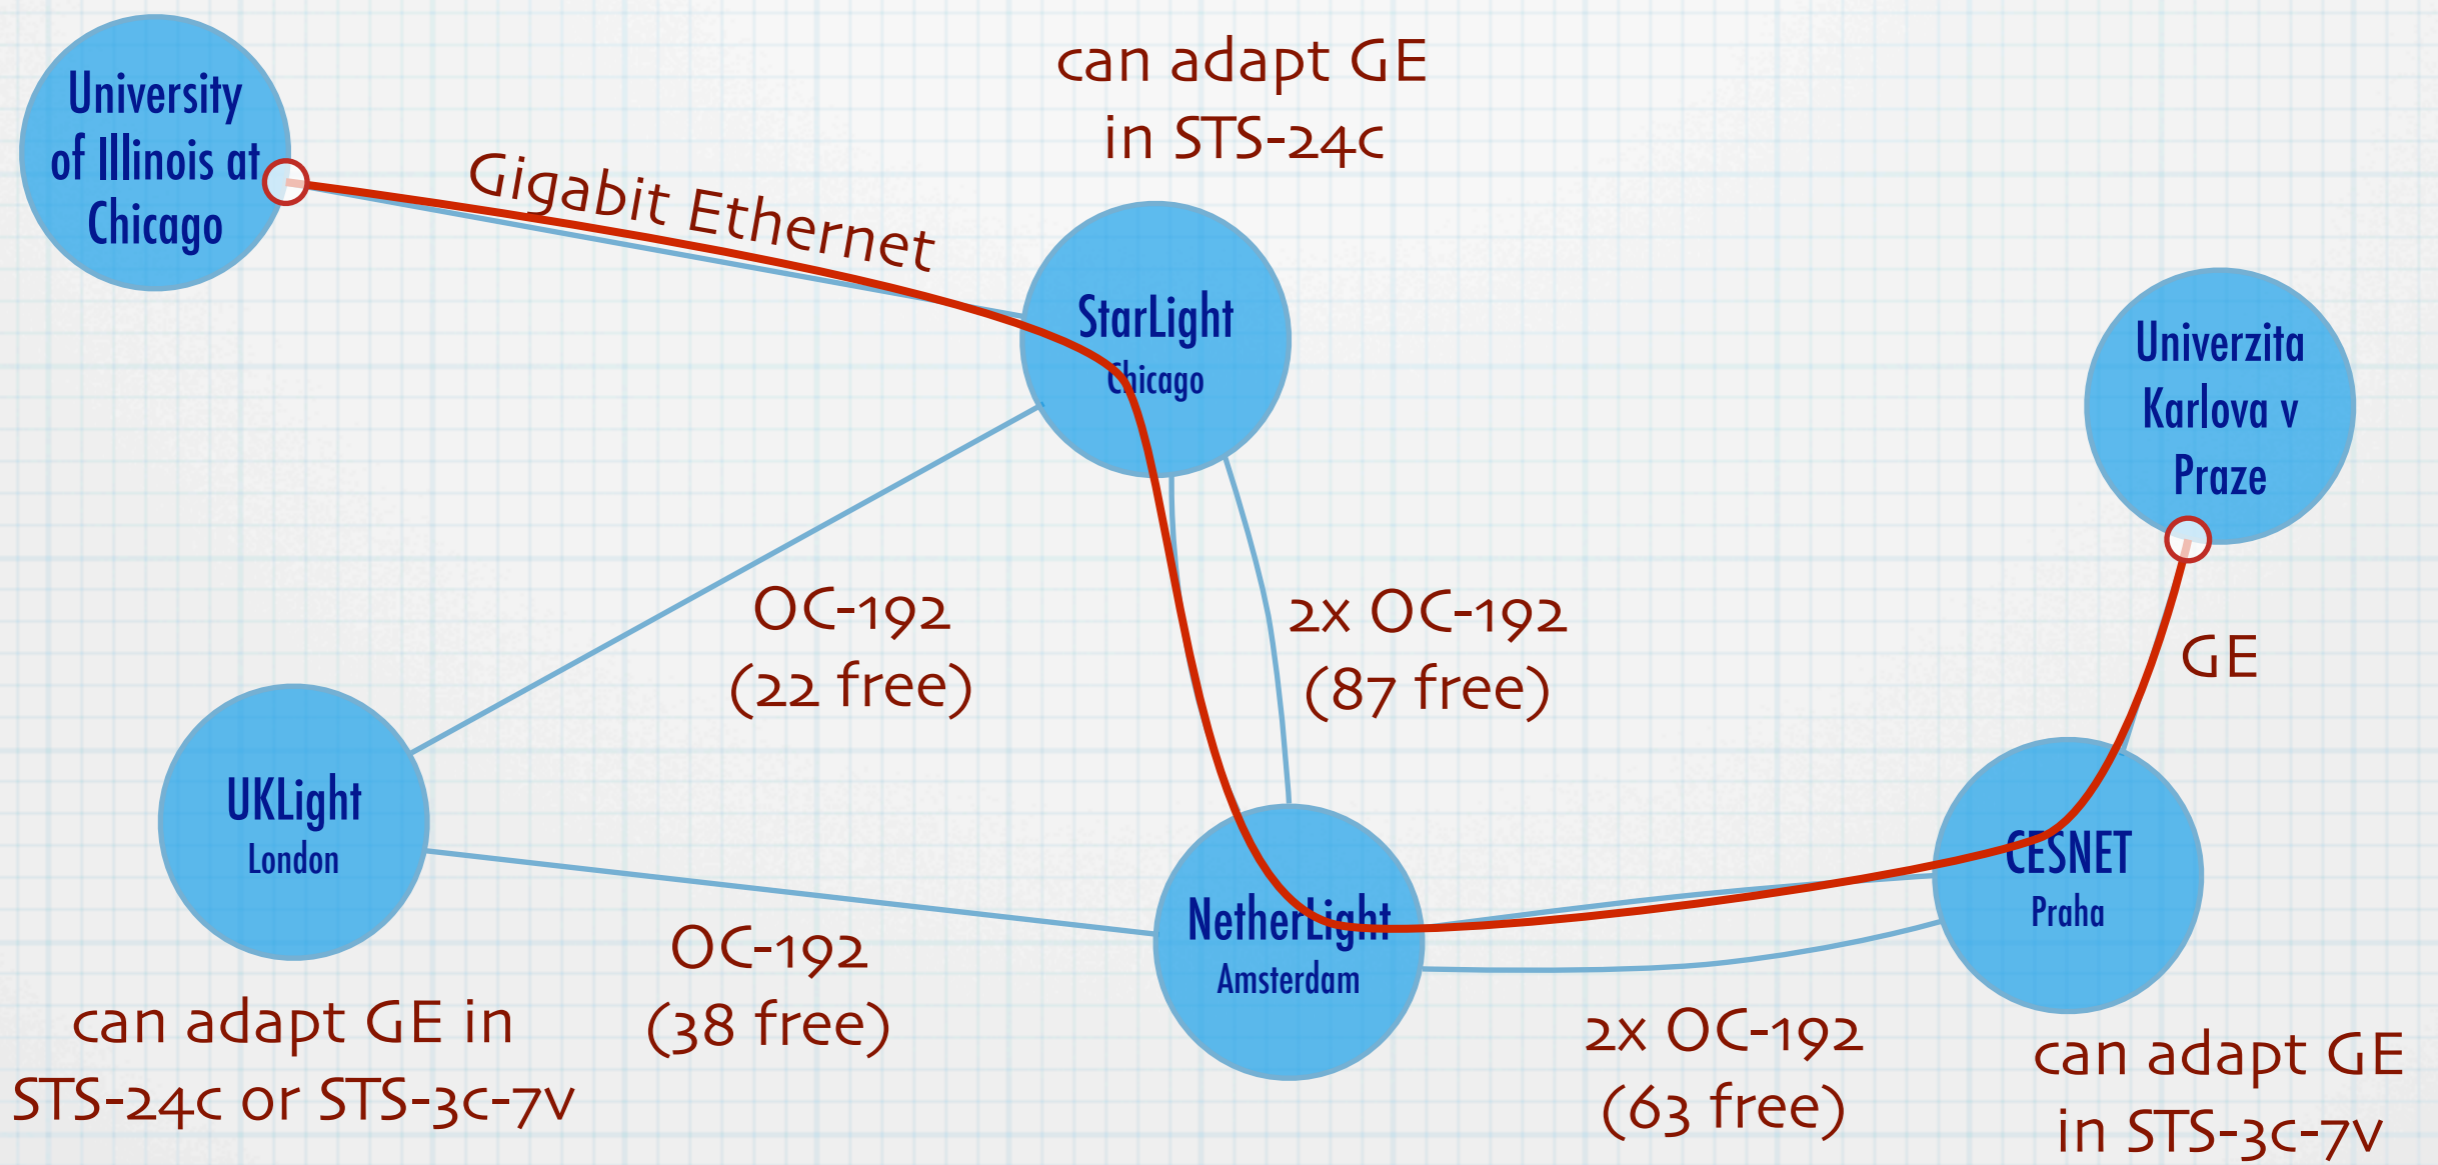

dinsdag 18 september 2007

This is our network. It's an example based on a practical problem in the GLIF about 2004. Hybrid: different technologies/layers. Different adaptations between layers. Not all available. Question for the network engineers in the audience: please find the shortest working path from University of Illinois at Chicago to Charles University in Prague.

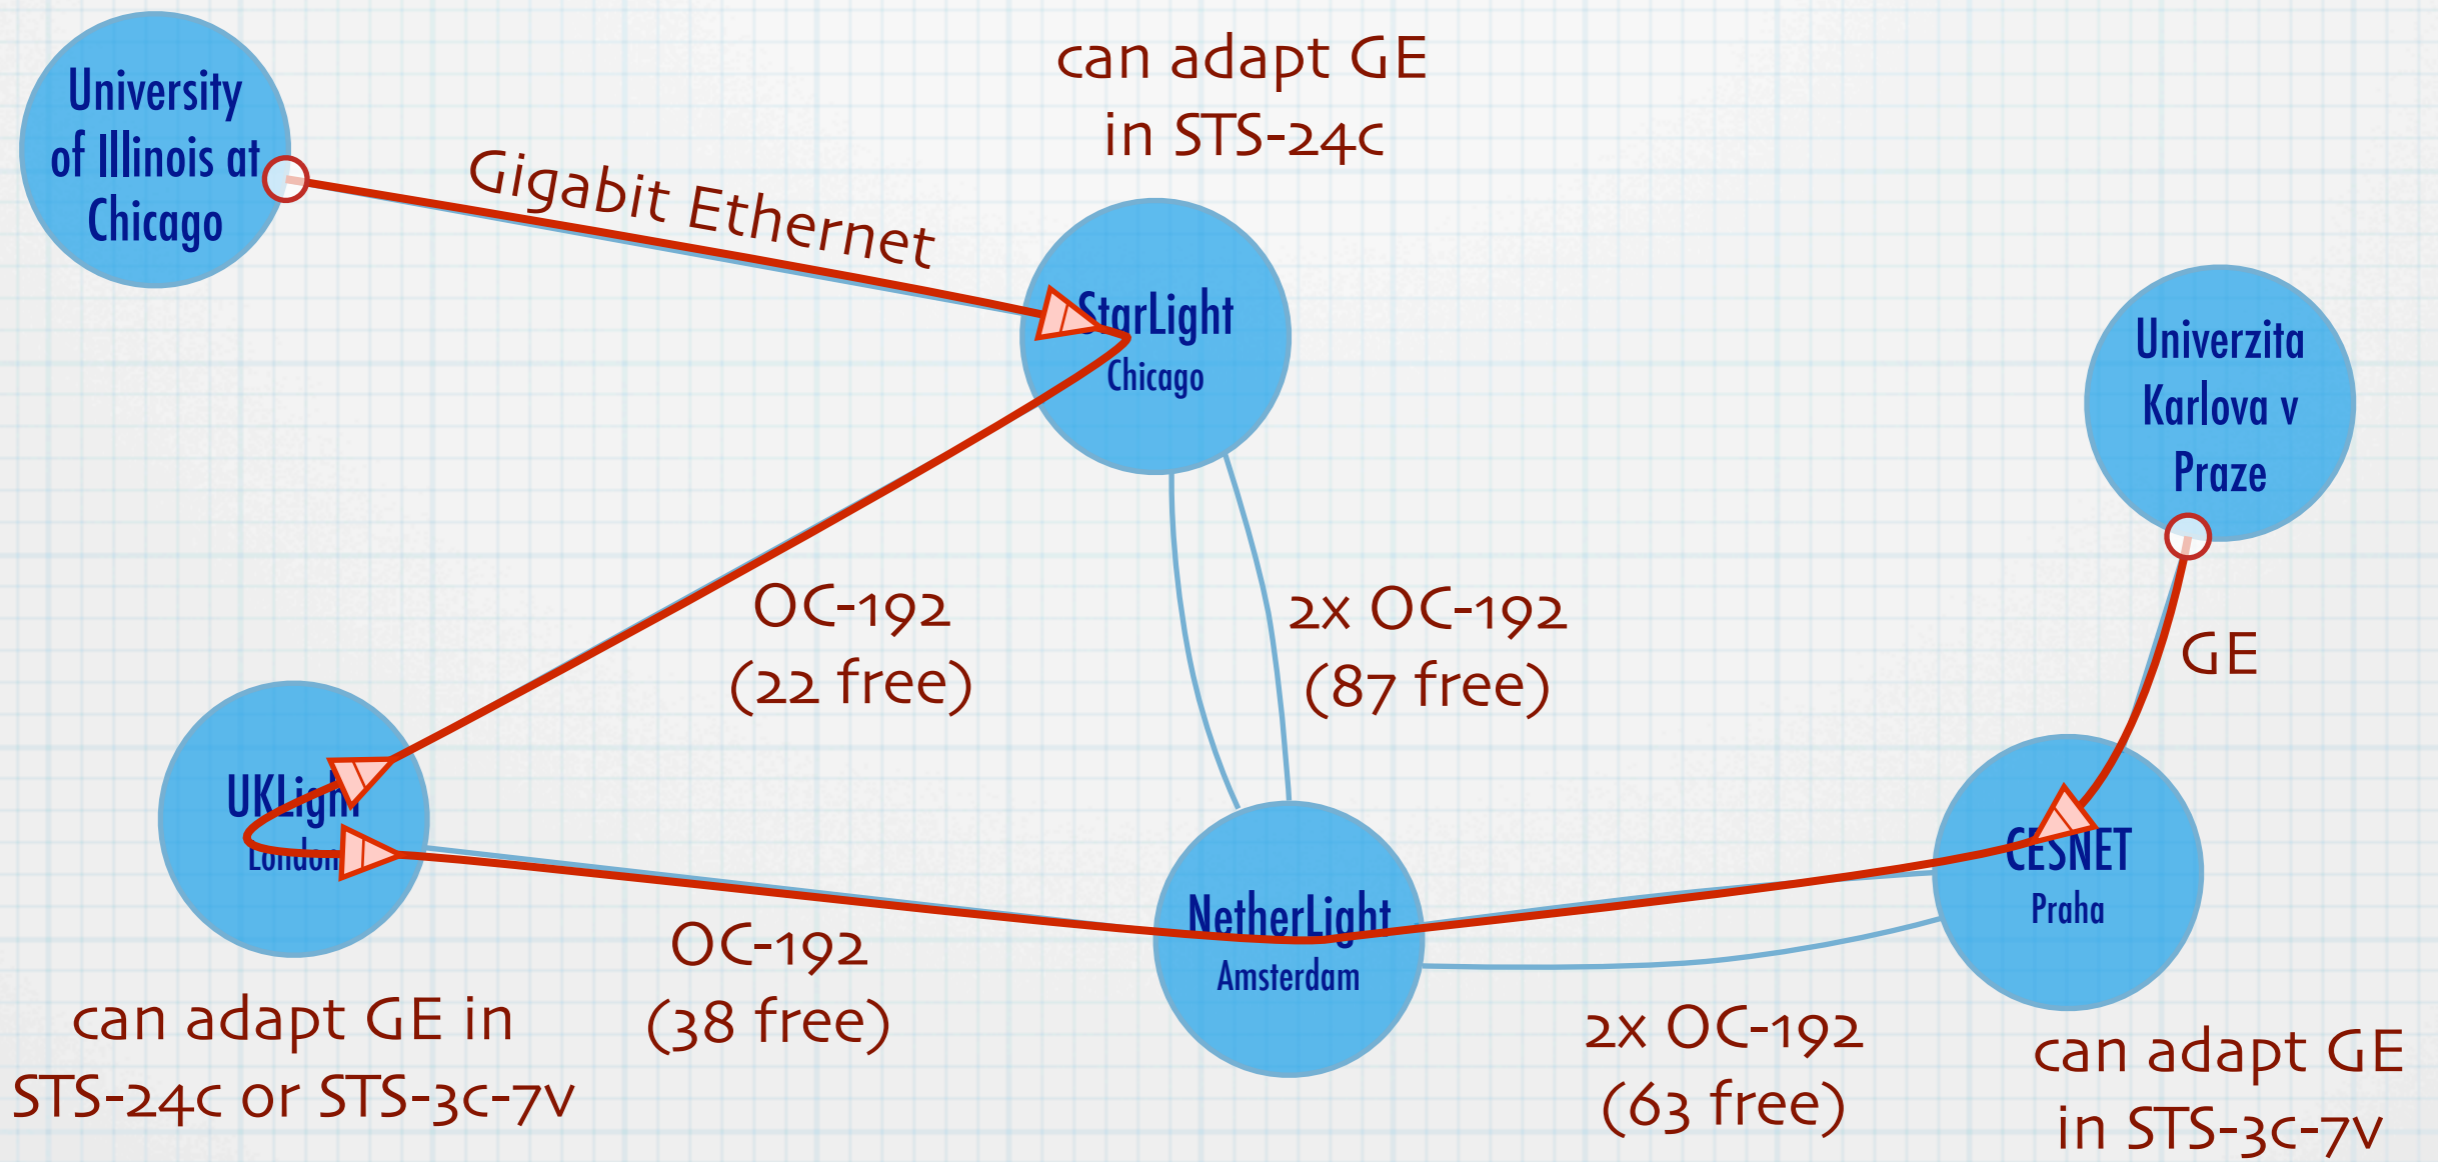

dinsdag 18 september 2007

This is our network. It's an example based on a practical problem in the GLIF about 2004. Hybrid: different technologies/layers. Different adaptations between layers. Not all available. Question for the network engineers in the audience: please find the shortest working path from University of Illinois at Chicago to Charles University in Prague.

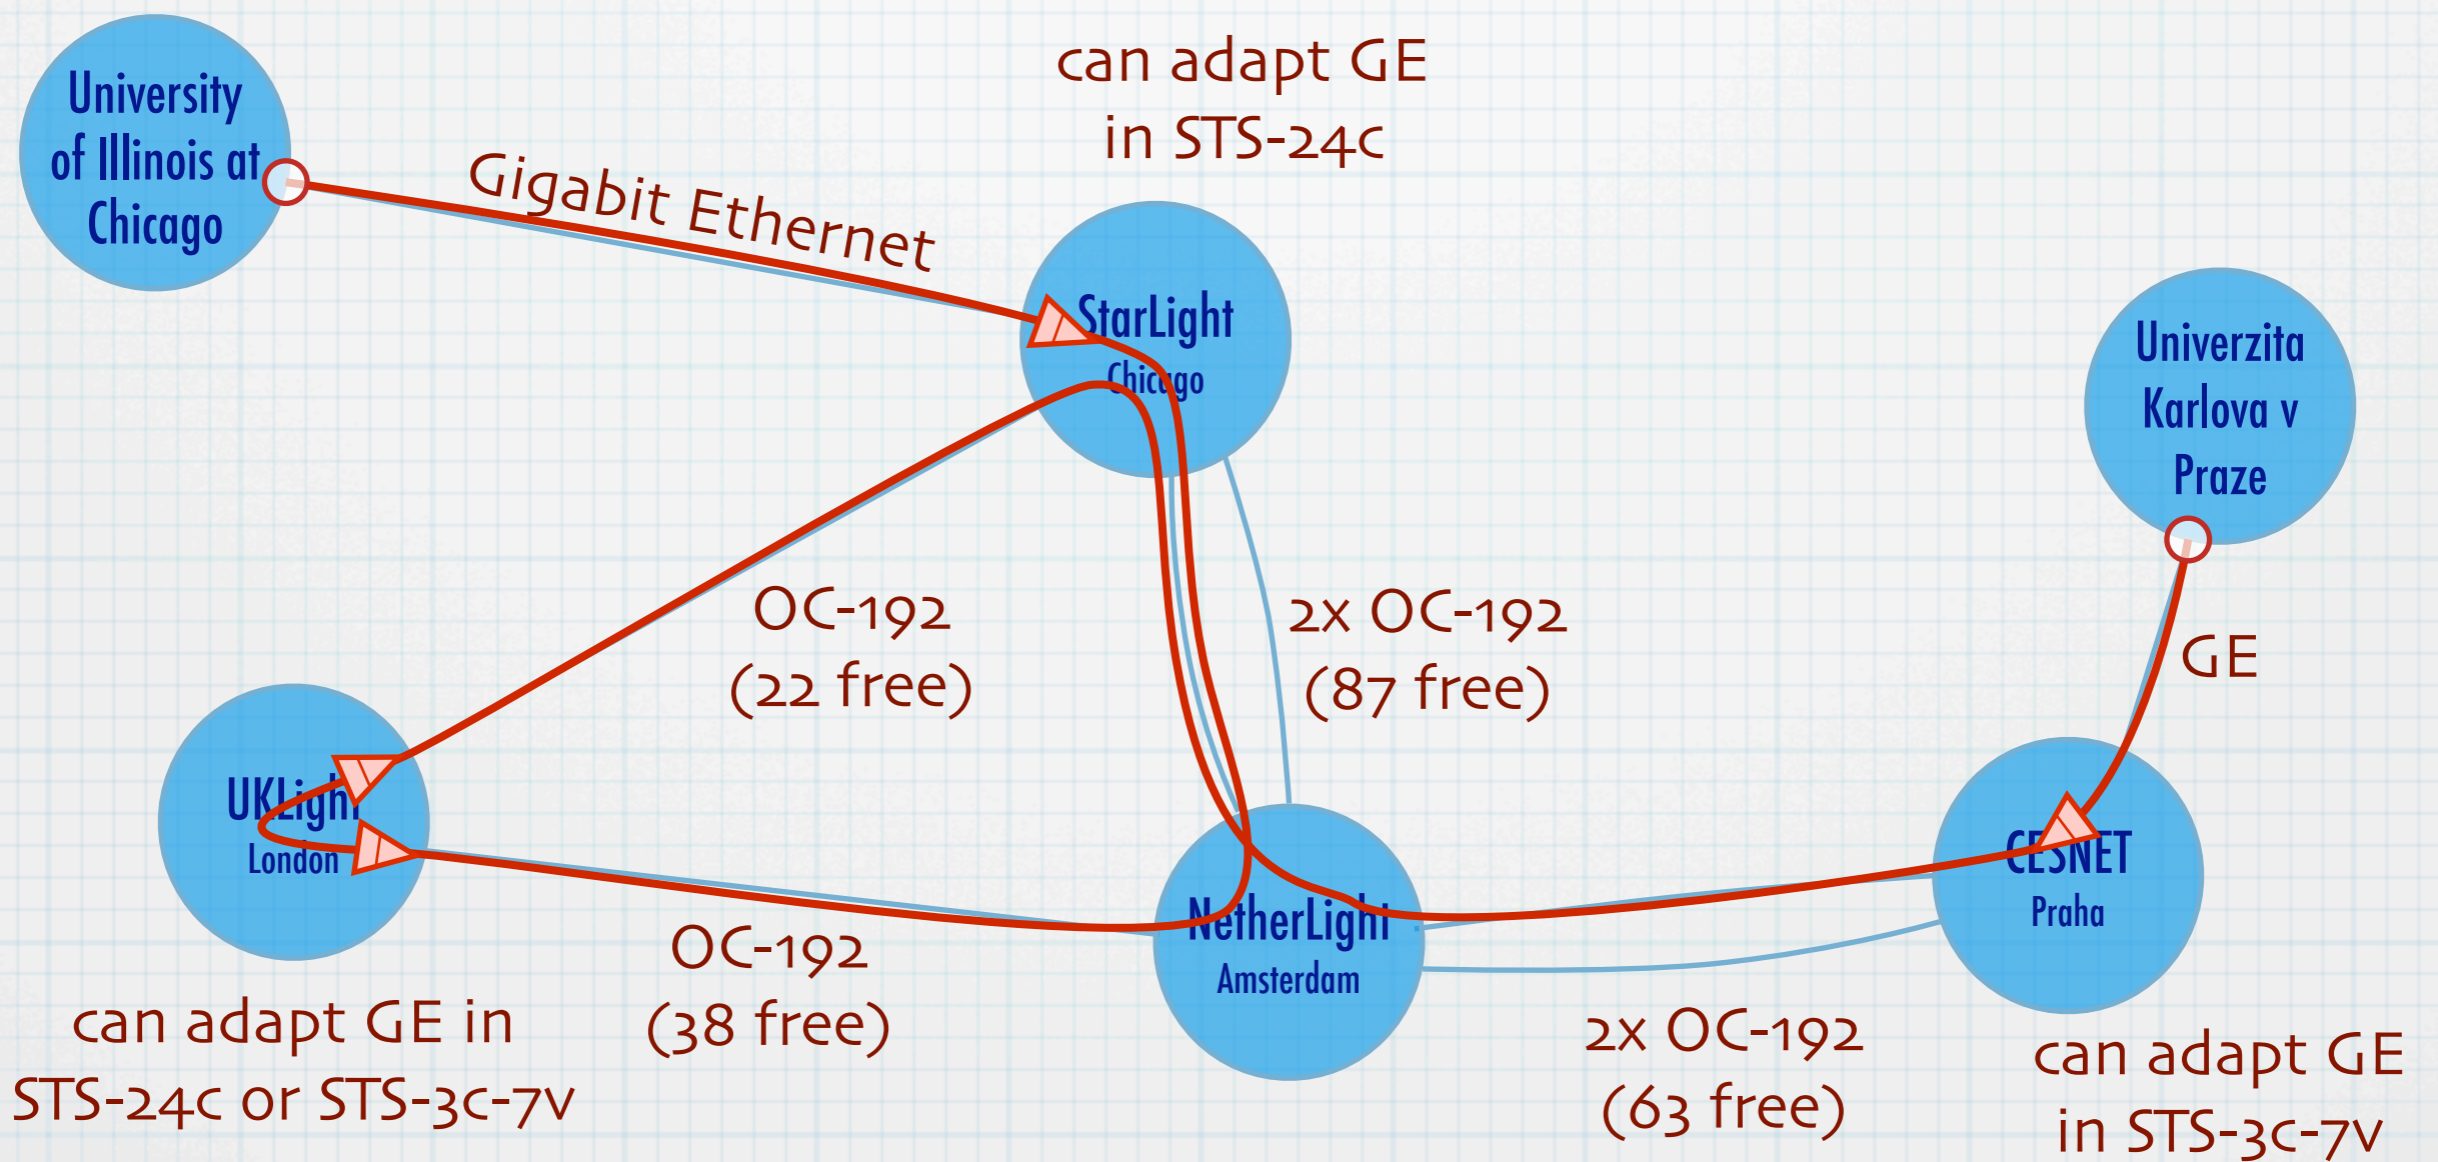

dinsdag 18 september 2007

First attempt: shortest path if you consider this as a graph.
 Link constraints don't work: every path is available.

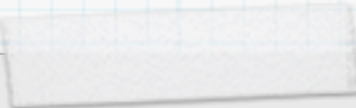

dinsdag 18 september 2007

We need to take adaptation into account: StarLight and CESNET use different adaptations of GE in STS channels.

dinsdag 18 september 2007

This is the shortest path through this network. You can not just consider one layer in this example: Quebec and Amsterdam do not even know about SDH. NetherLight does not understand Ethernet. Adaptations are important. We need a new "Dijkstra".

Create a computer-readable network description, that provides enough information for path finding in multi-layer networks

Goal

The Modelling Process

Network Elements

Functional Elements

Syntax

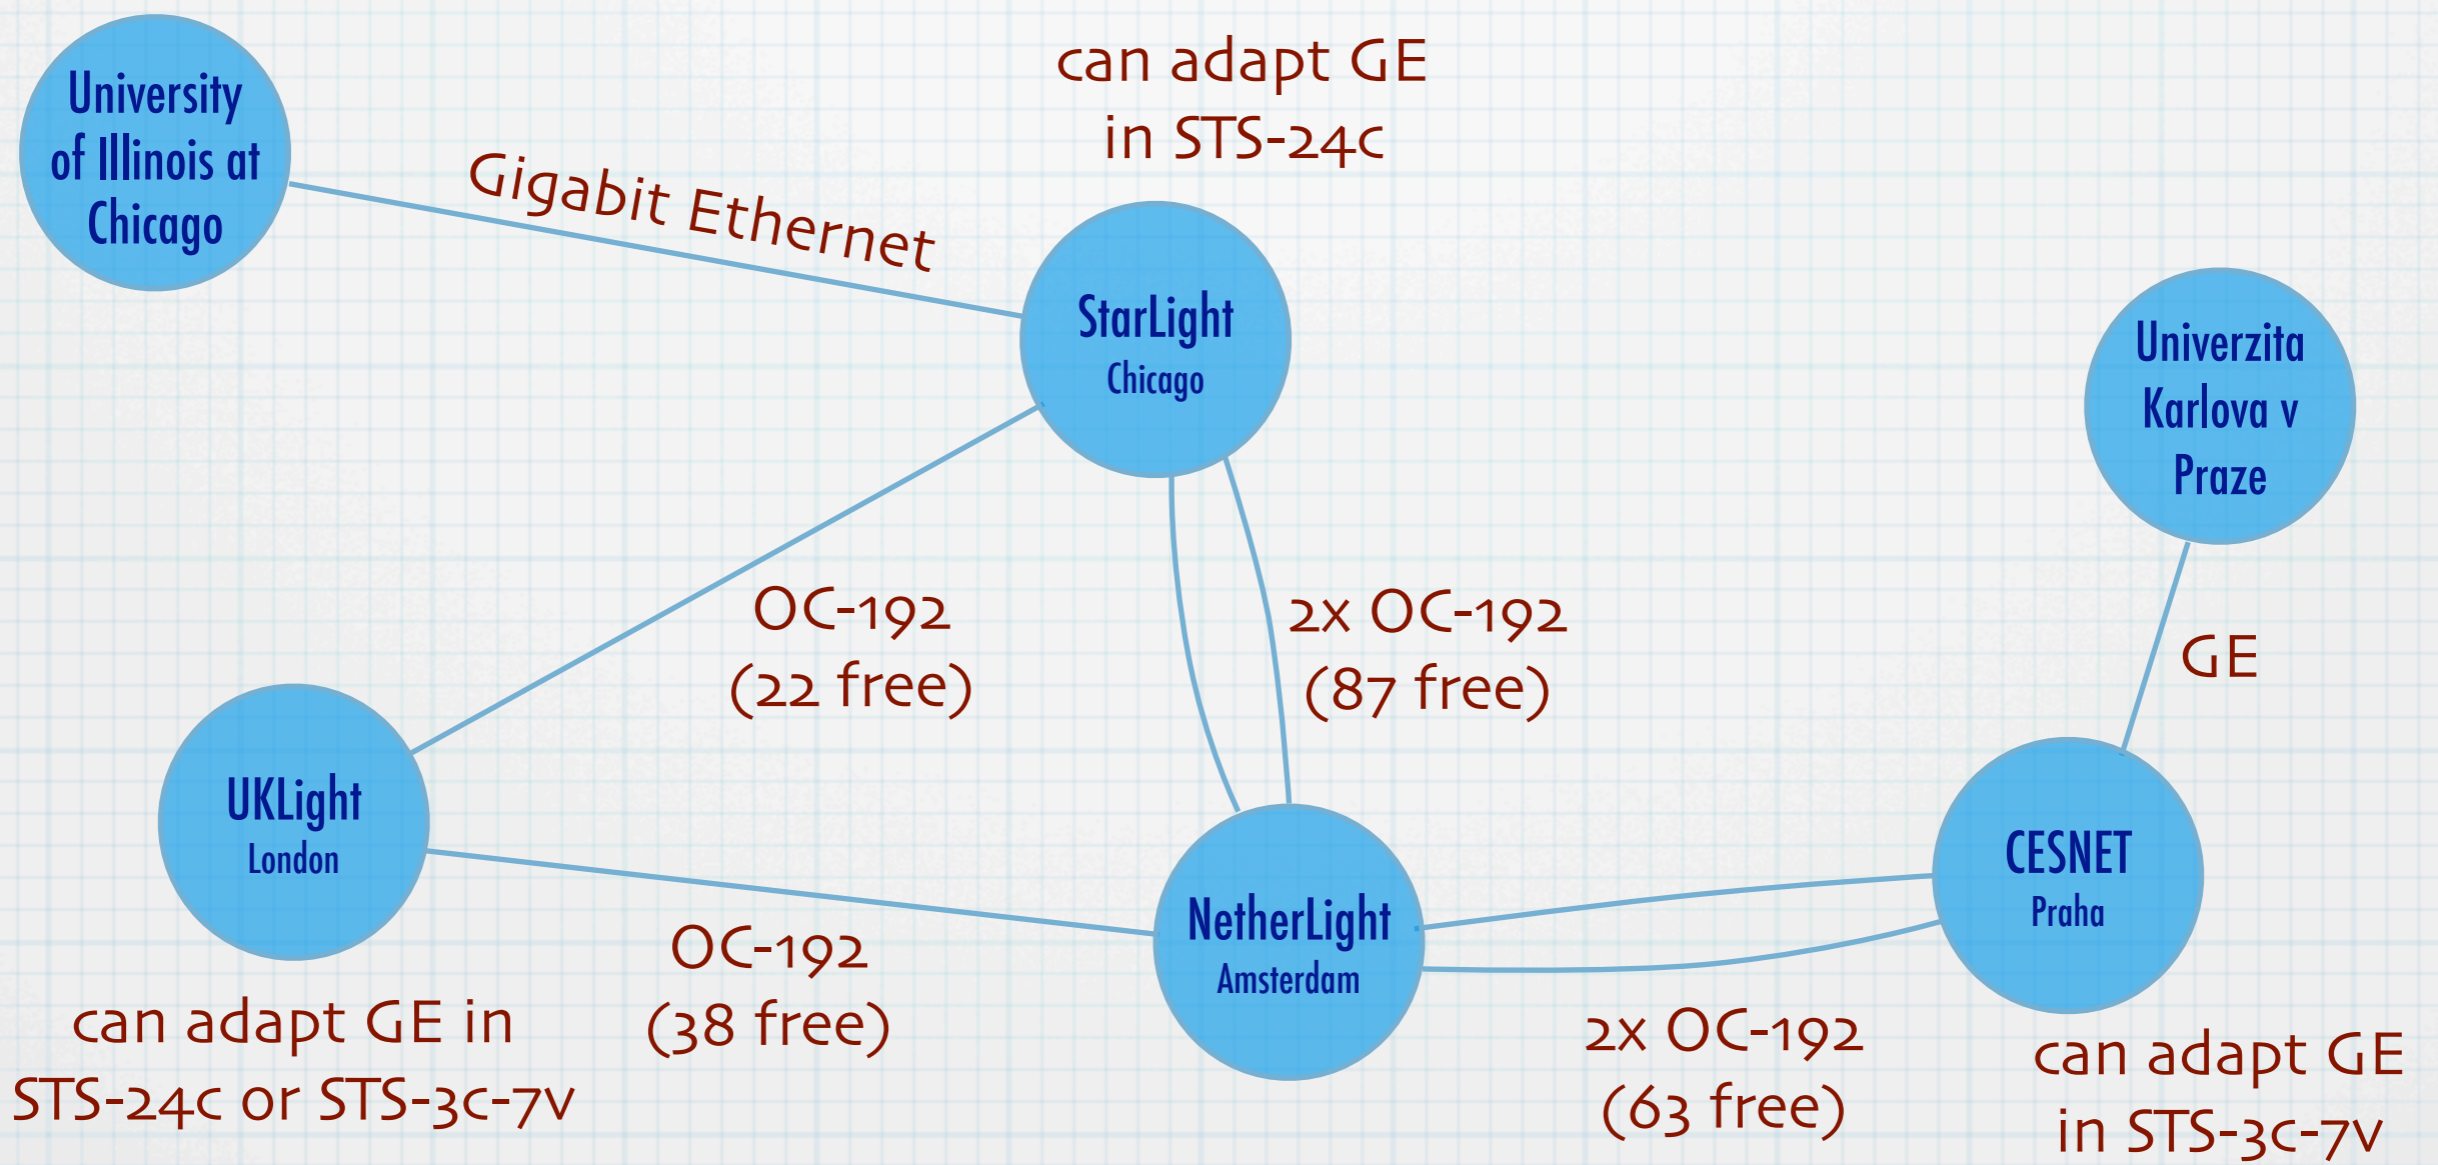

```
<ndl:Device rdf:about="#Force10">
  <ndl:hasInterface rdf:resource=
    "#Force10:te6/0"/>
</ndl:Device>
<ndl:Interface rdf:about="#Force10:te6/0">
  <rdfs:label>te6/0</rdfs:label>
  <ndl:capacity>1.25E6</ndl:capacity>
  <ndlconf:multiplex>
    <ndlcap:adaptation rdf:resource=
      "#Tagged-Ethernet-in-Ethernet"/>
    <ndlconf:serverPropertyValue
      rdf:resource="#MTU-1500byte"/>
  </ndlconf:multiplex>
  <ndlconf:hasChannel>
    <ndlconf:Channel rdf:about=
      "#Force10:te6/0:vlan4">
      <ndleth:hasVlan>4</ndleth:hasVlan>
      <ndlconf:switchedTo rdf:resource=
        "#Force10:gi5/1:vlan7"/>
    </ndlconf:Channel>
  </ndlconf:hasChannel>
</ndl:Interface>
```

dinsdag 18 september 2007

Let's remind about the theory of modelling.

- Network elements: physical device
- Map to functional elements (e.g. G.805 elements)
- Rewrite that in a concise, but compact syntax (e.g. NDL)

dinsdag 18 september 2007

Task 1: Model (GMPLS + G.805): next few slides

Switching matrix

A device switches data based on:

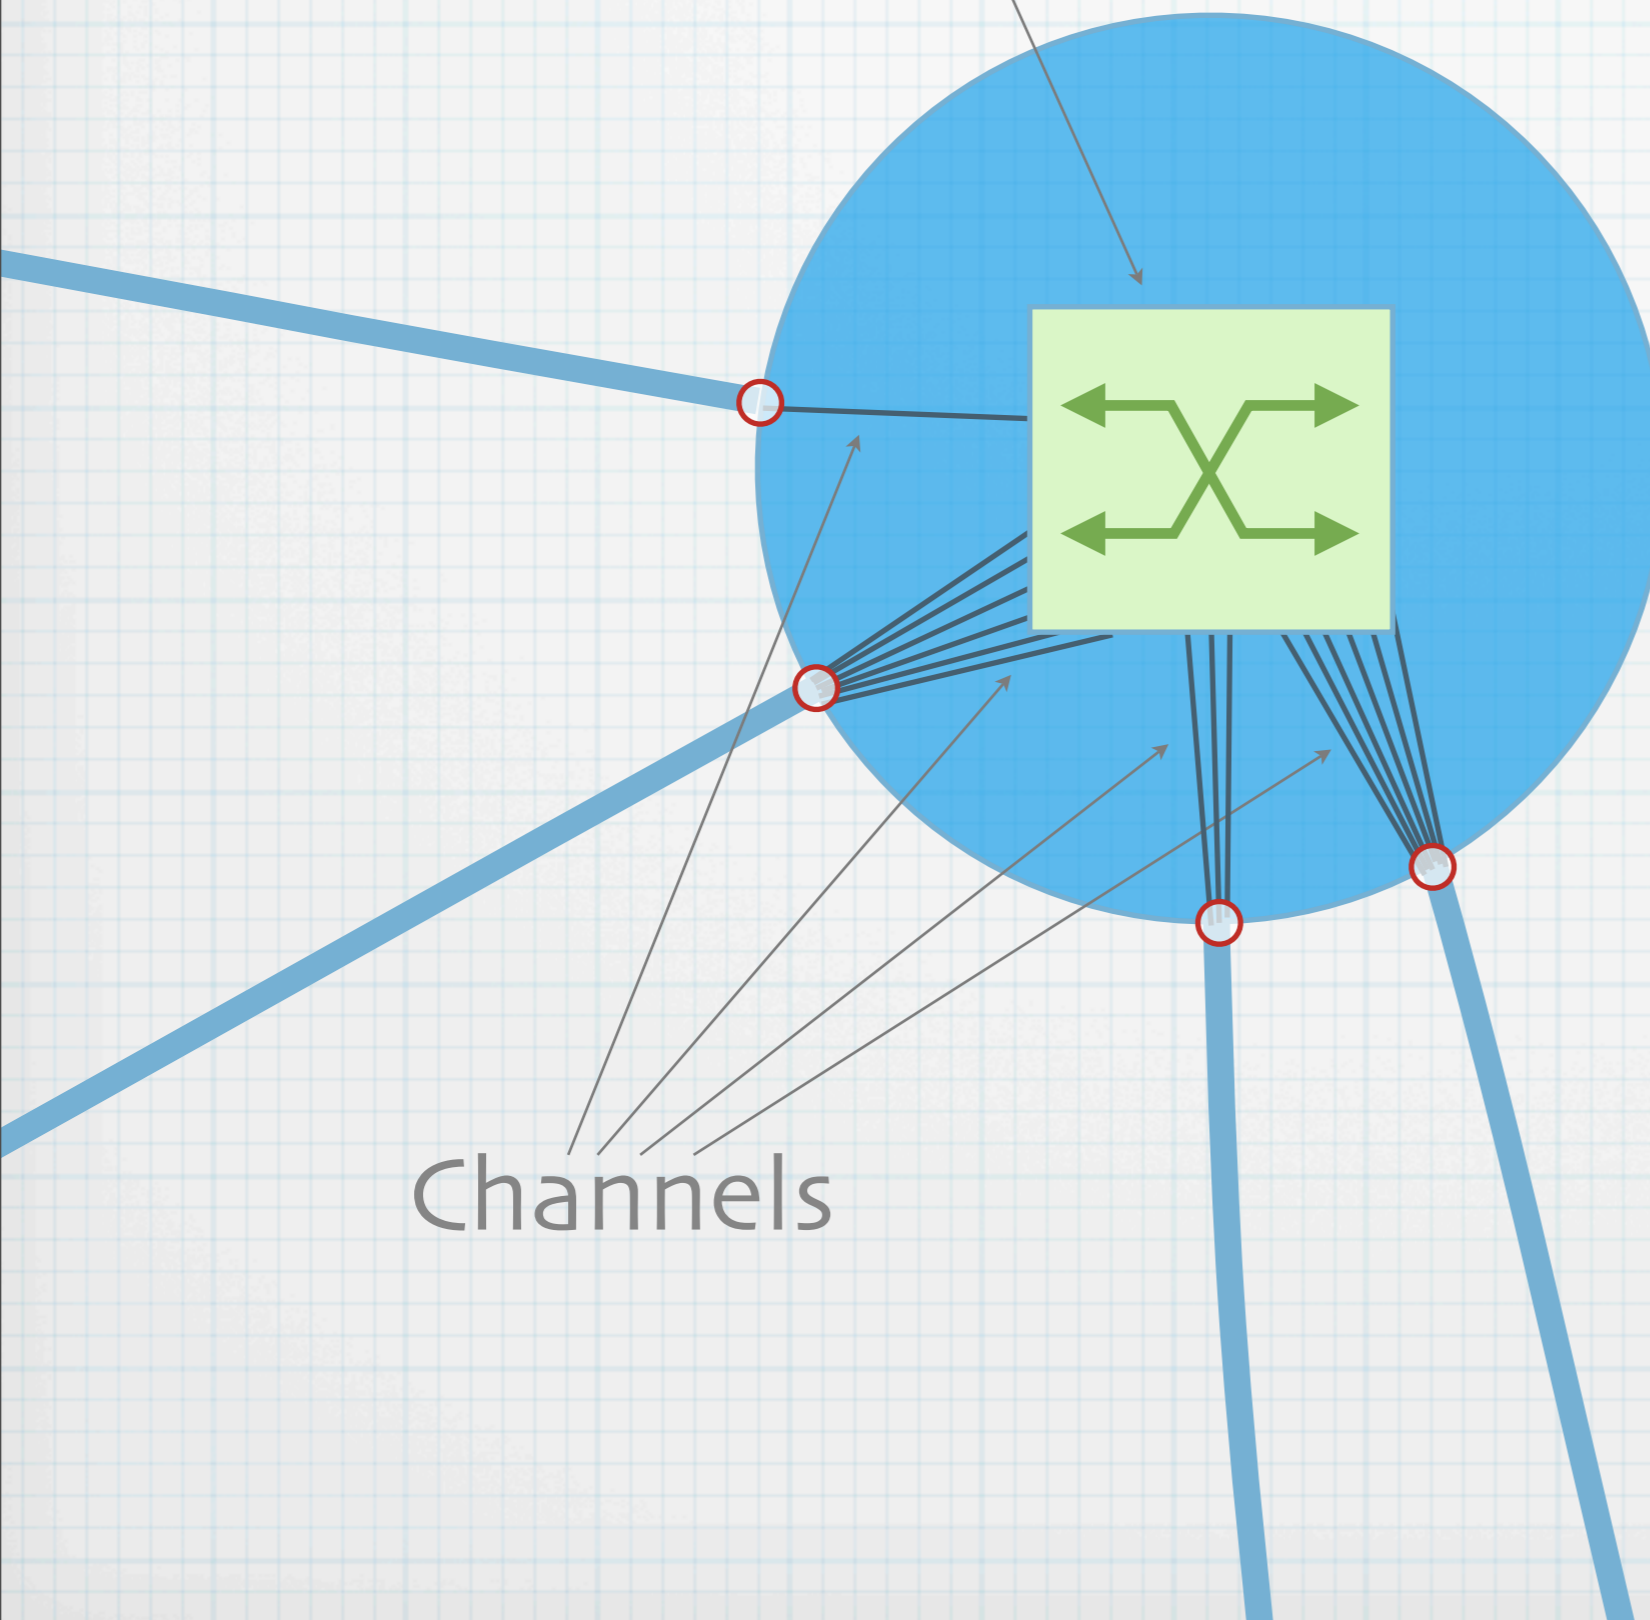

- The source interface
- One or more labels

Example label types:

- Ethernet VLAN
- SONET STS Channel
- Wavelength (λ)

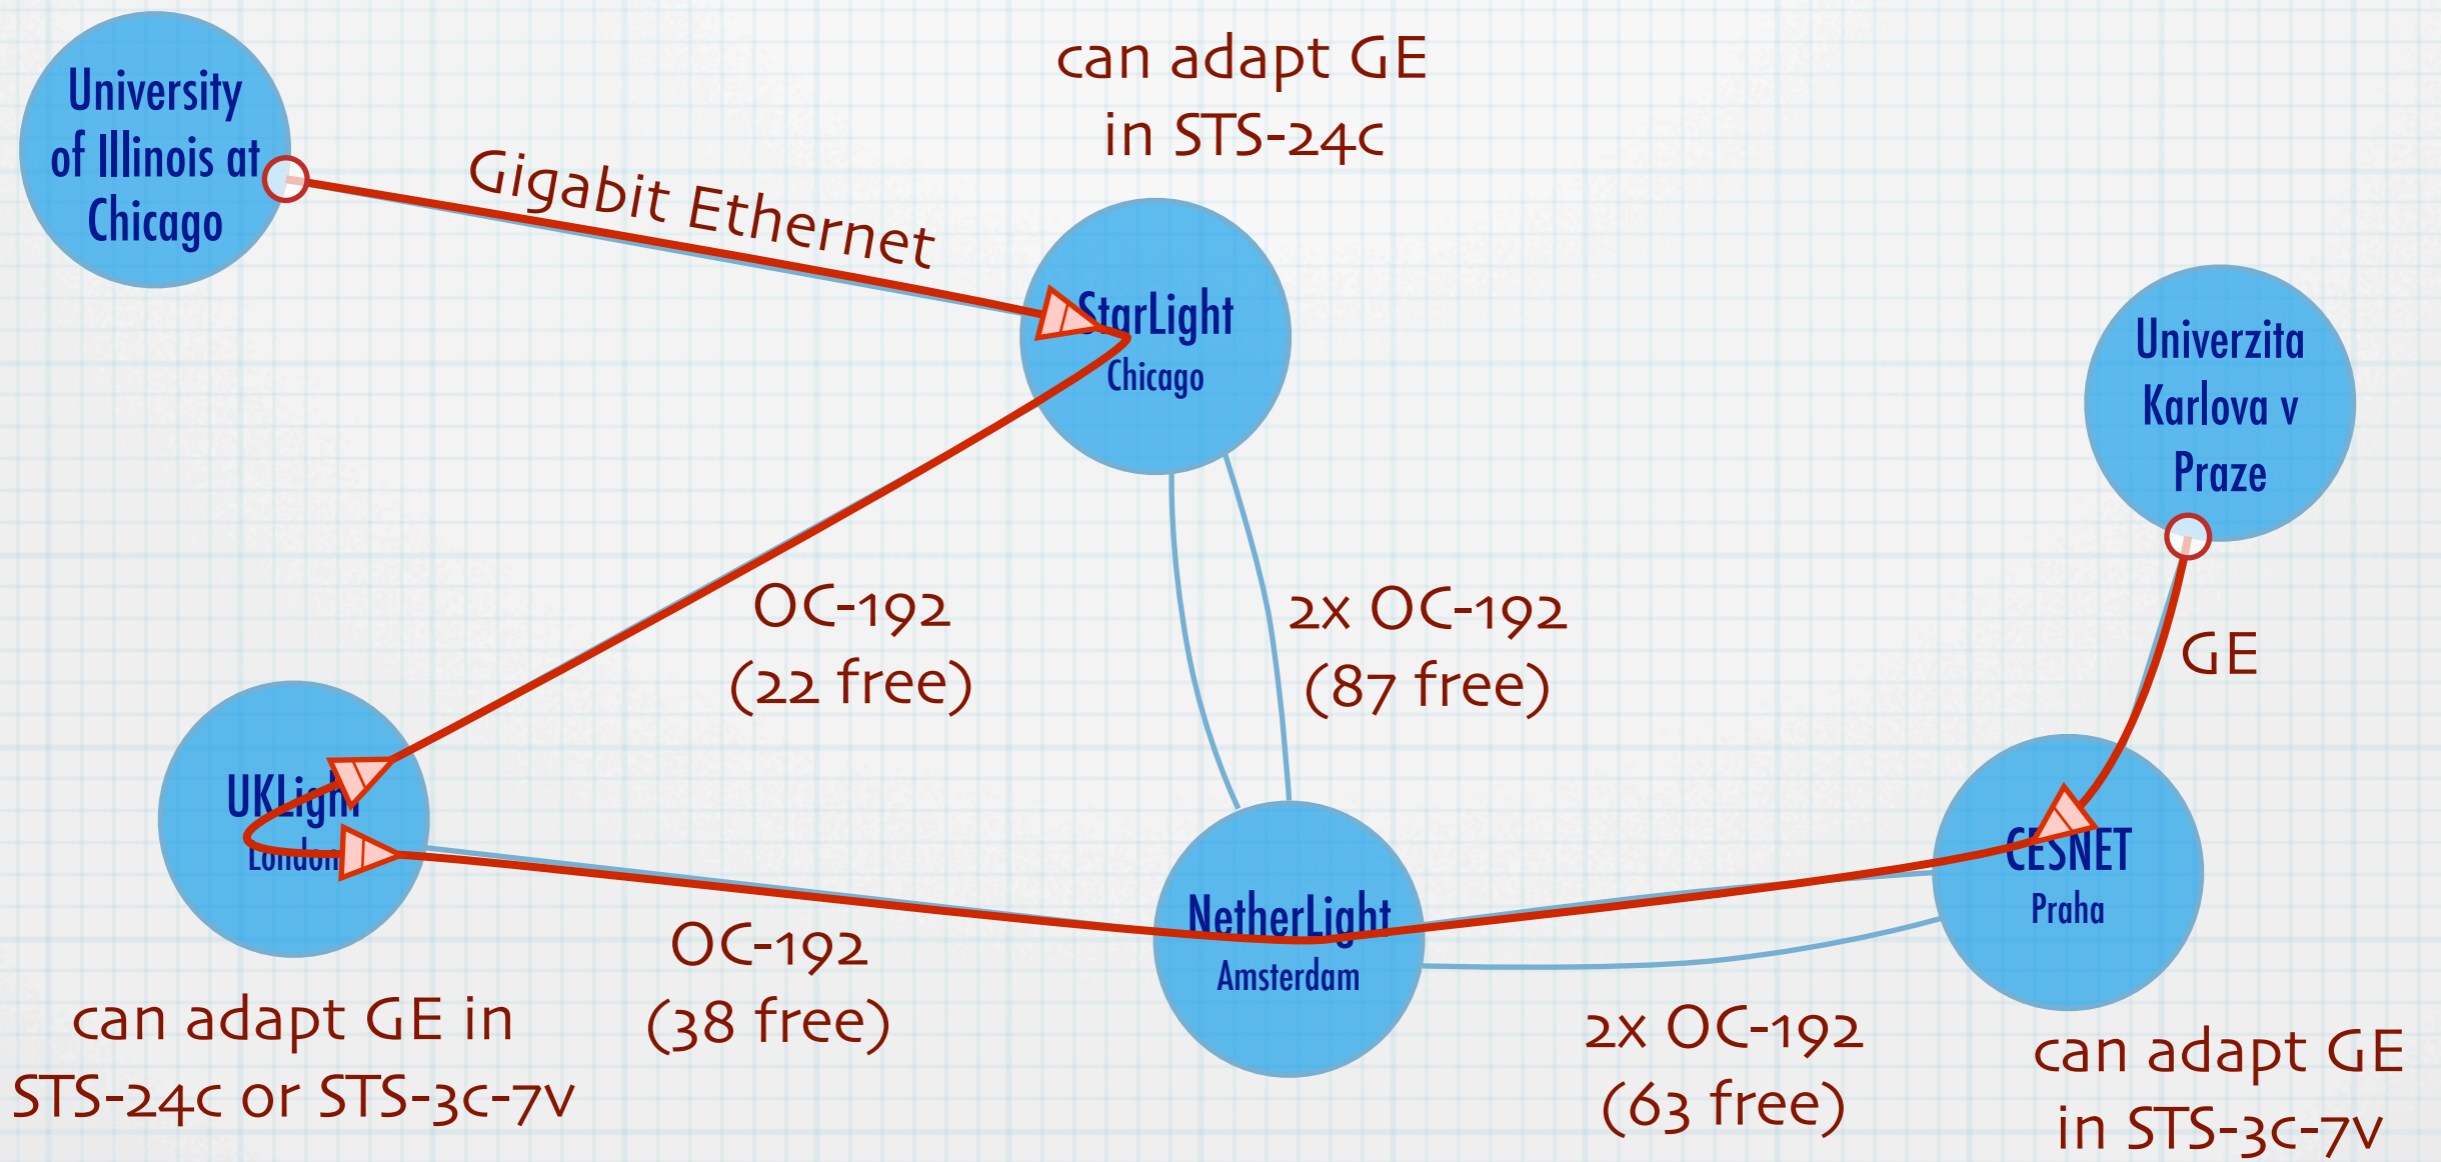

For example, all data from channel 31 of interface 2 is forwarded to channel 28 of interface 4.

Channels

dinsdag 18 september 2007

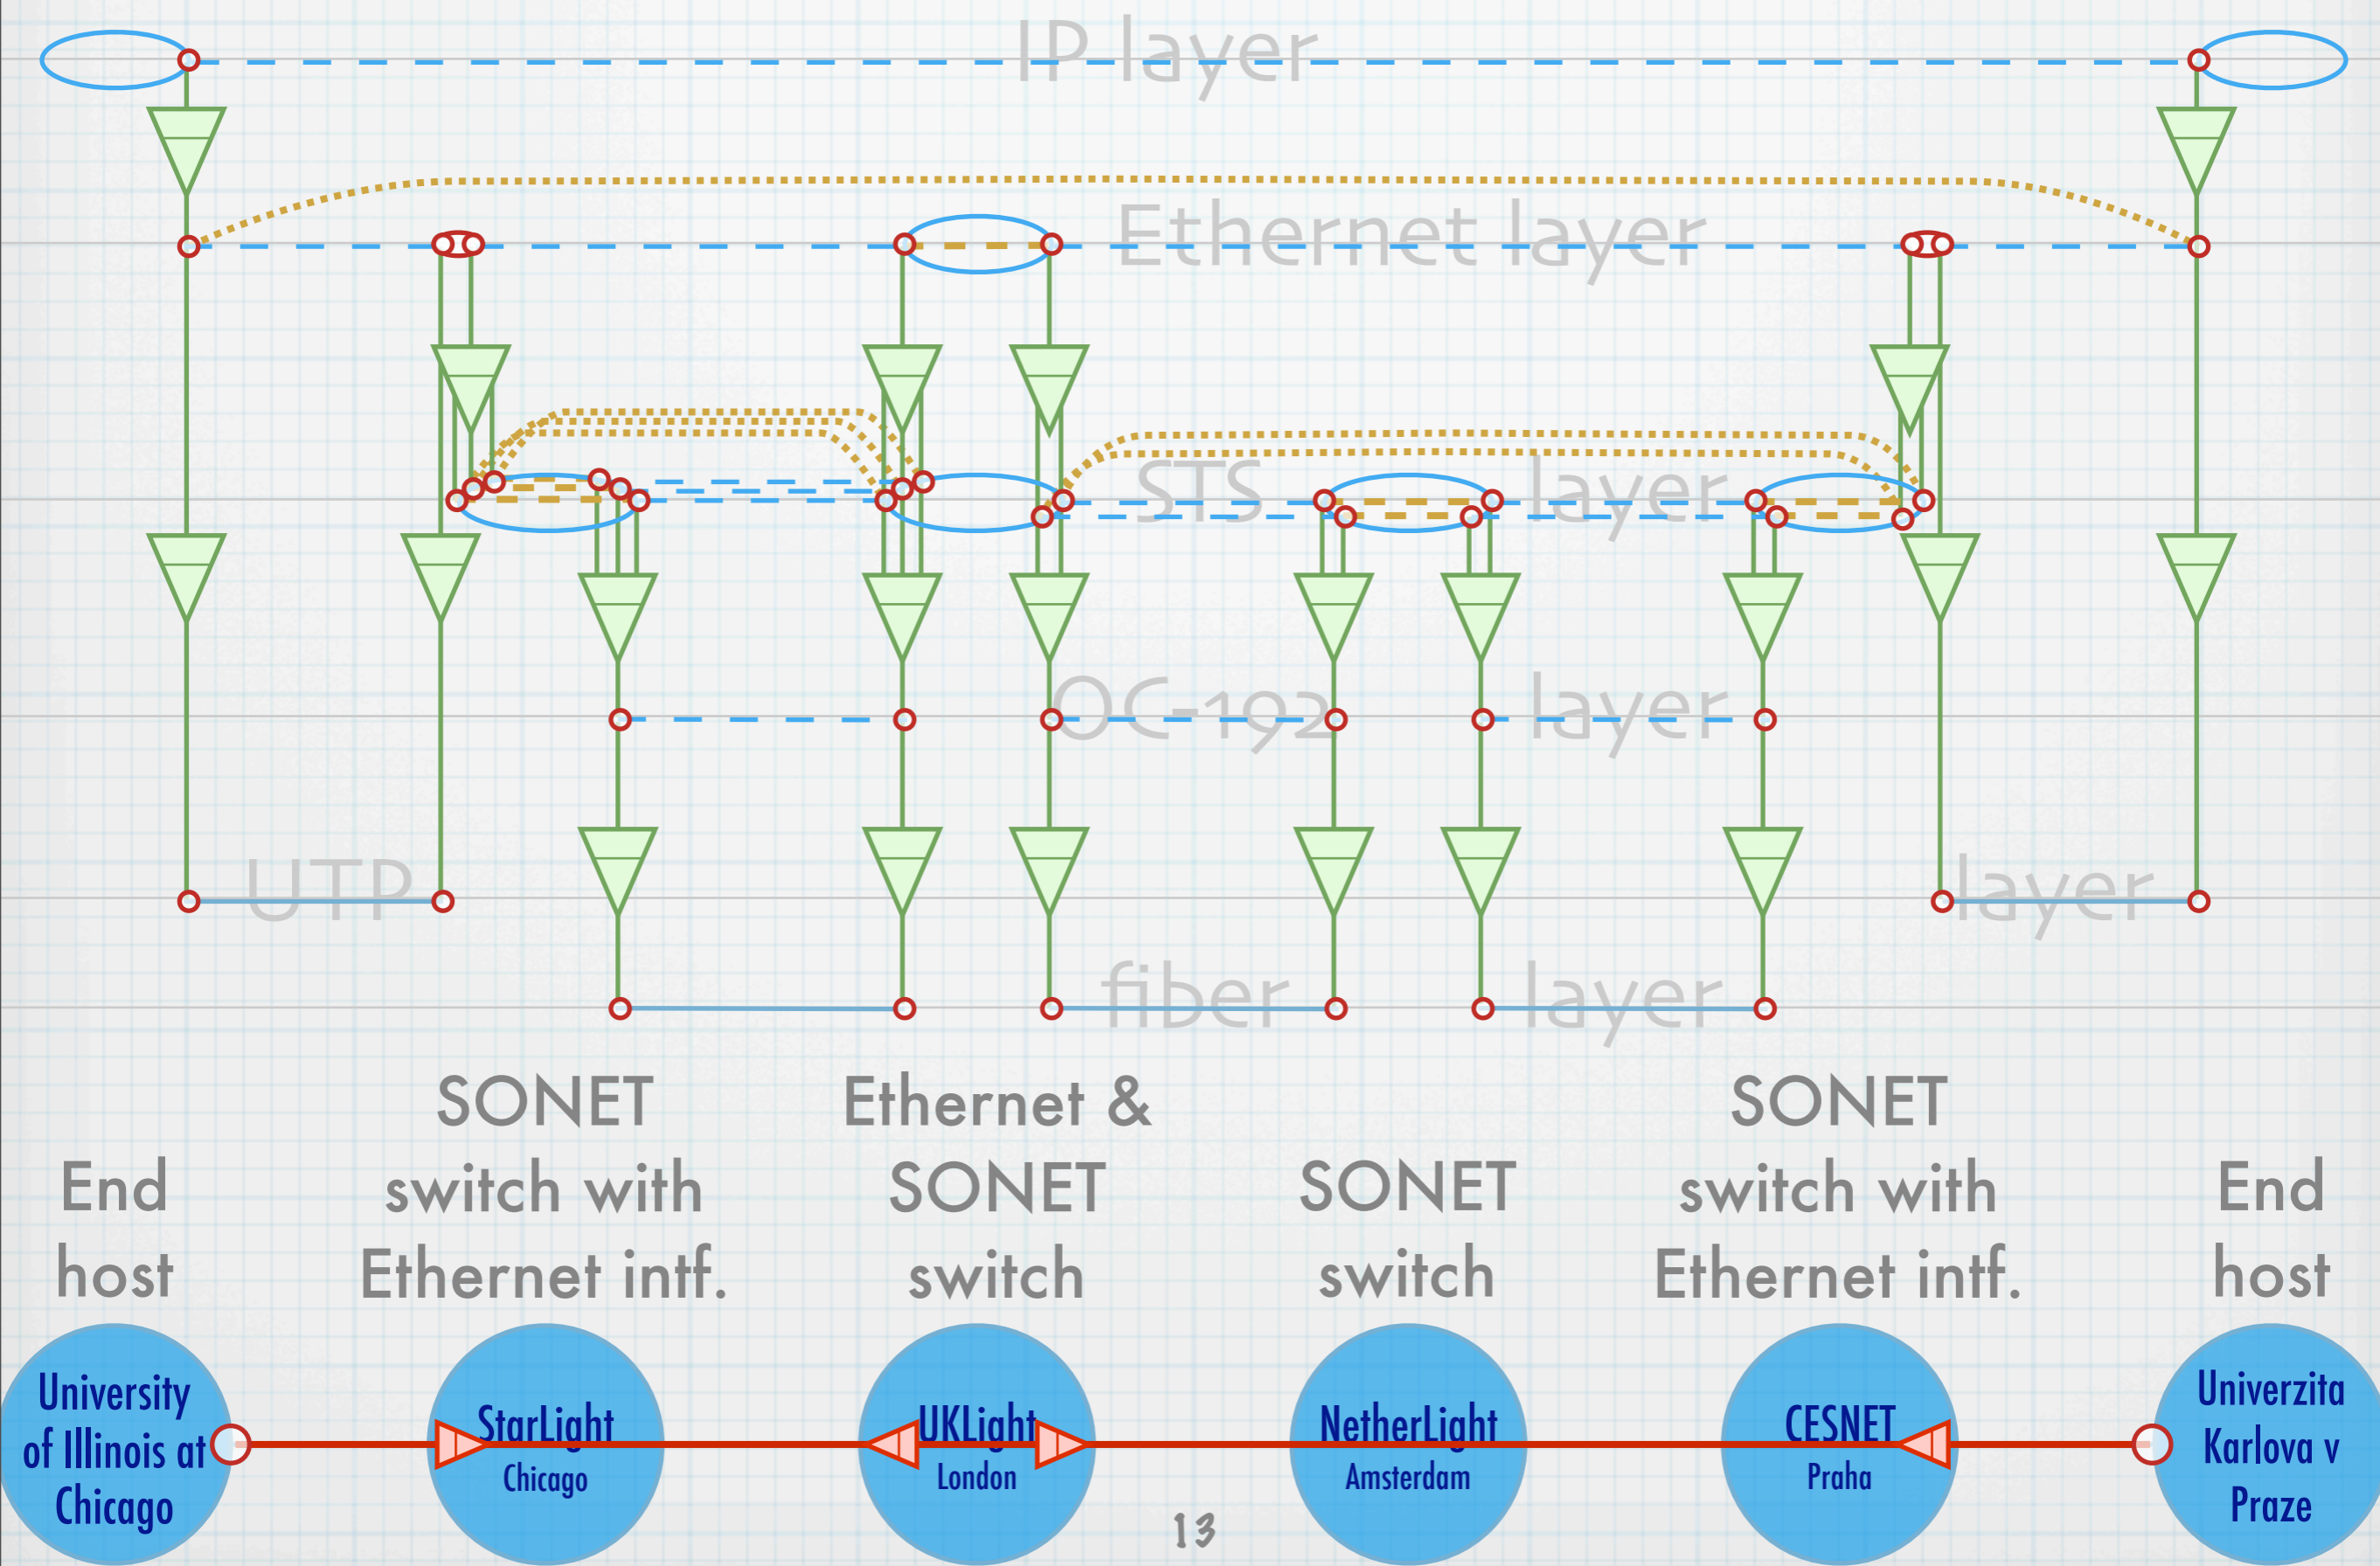

Core of a device is a switching matrix. Typically, every connected link is split (demuxed) into multiple channels, each of which is connected to the switching matrix. Any property that is used to make a switching decision is a label type. GMPLS concept.

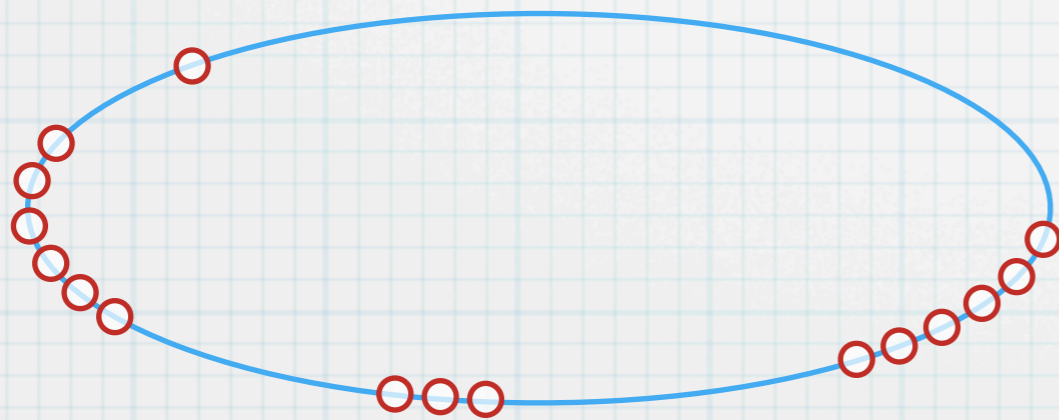

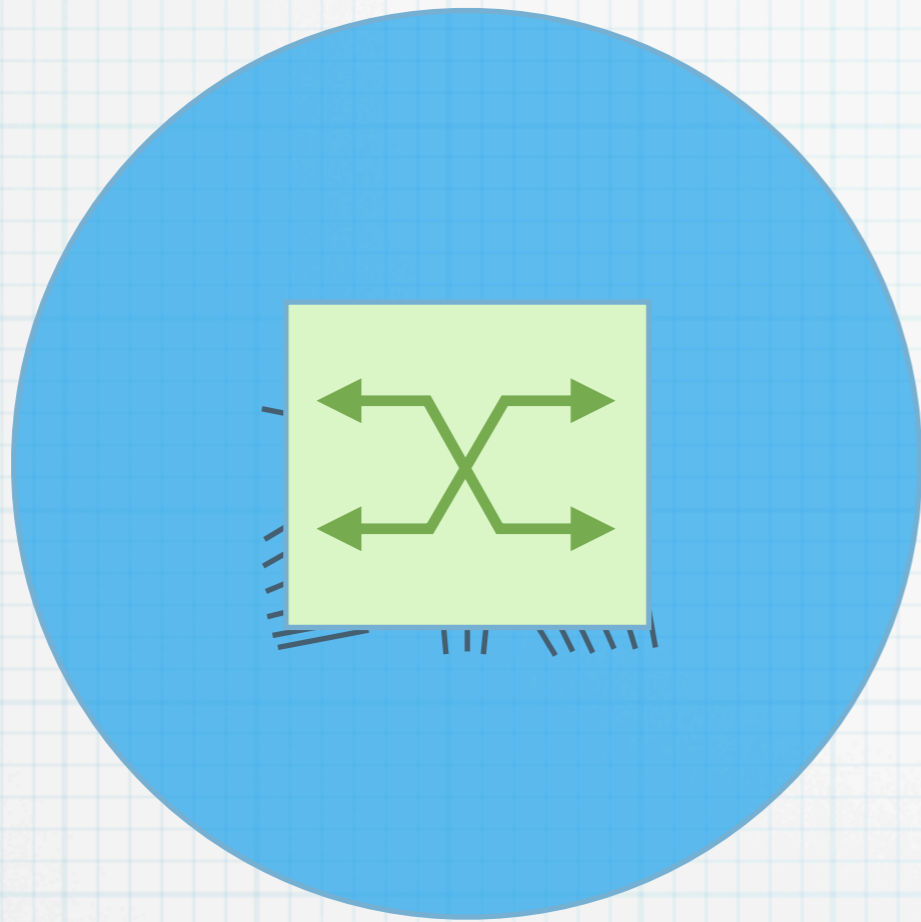

dinsdag 18 september 2007

G.805. Let's go back to our second attempt and examine the adaptation incompatibilities.

We use G.805 functional elements for our information model. subnetwork, connection points (few per interface), adaptation (+termination) functions, links, link connections, subnetwork connections (configuration), network connections. In addition, we use the label concept of GMPLS (not explained in presentation).

Subnetwork with 433
connection points

Device

switchingCapability → **LabelType**

Can switch, but not change label.
E.g. from STS 31 of interface 2 to
STS 31 of interface 4.

swappingCapability → **LabelType**

Can change label.
E.g. from STS 31 of interface 2 to
STS 28 of interface 4.

Interface

hasLabel → **Label**

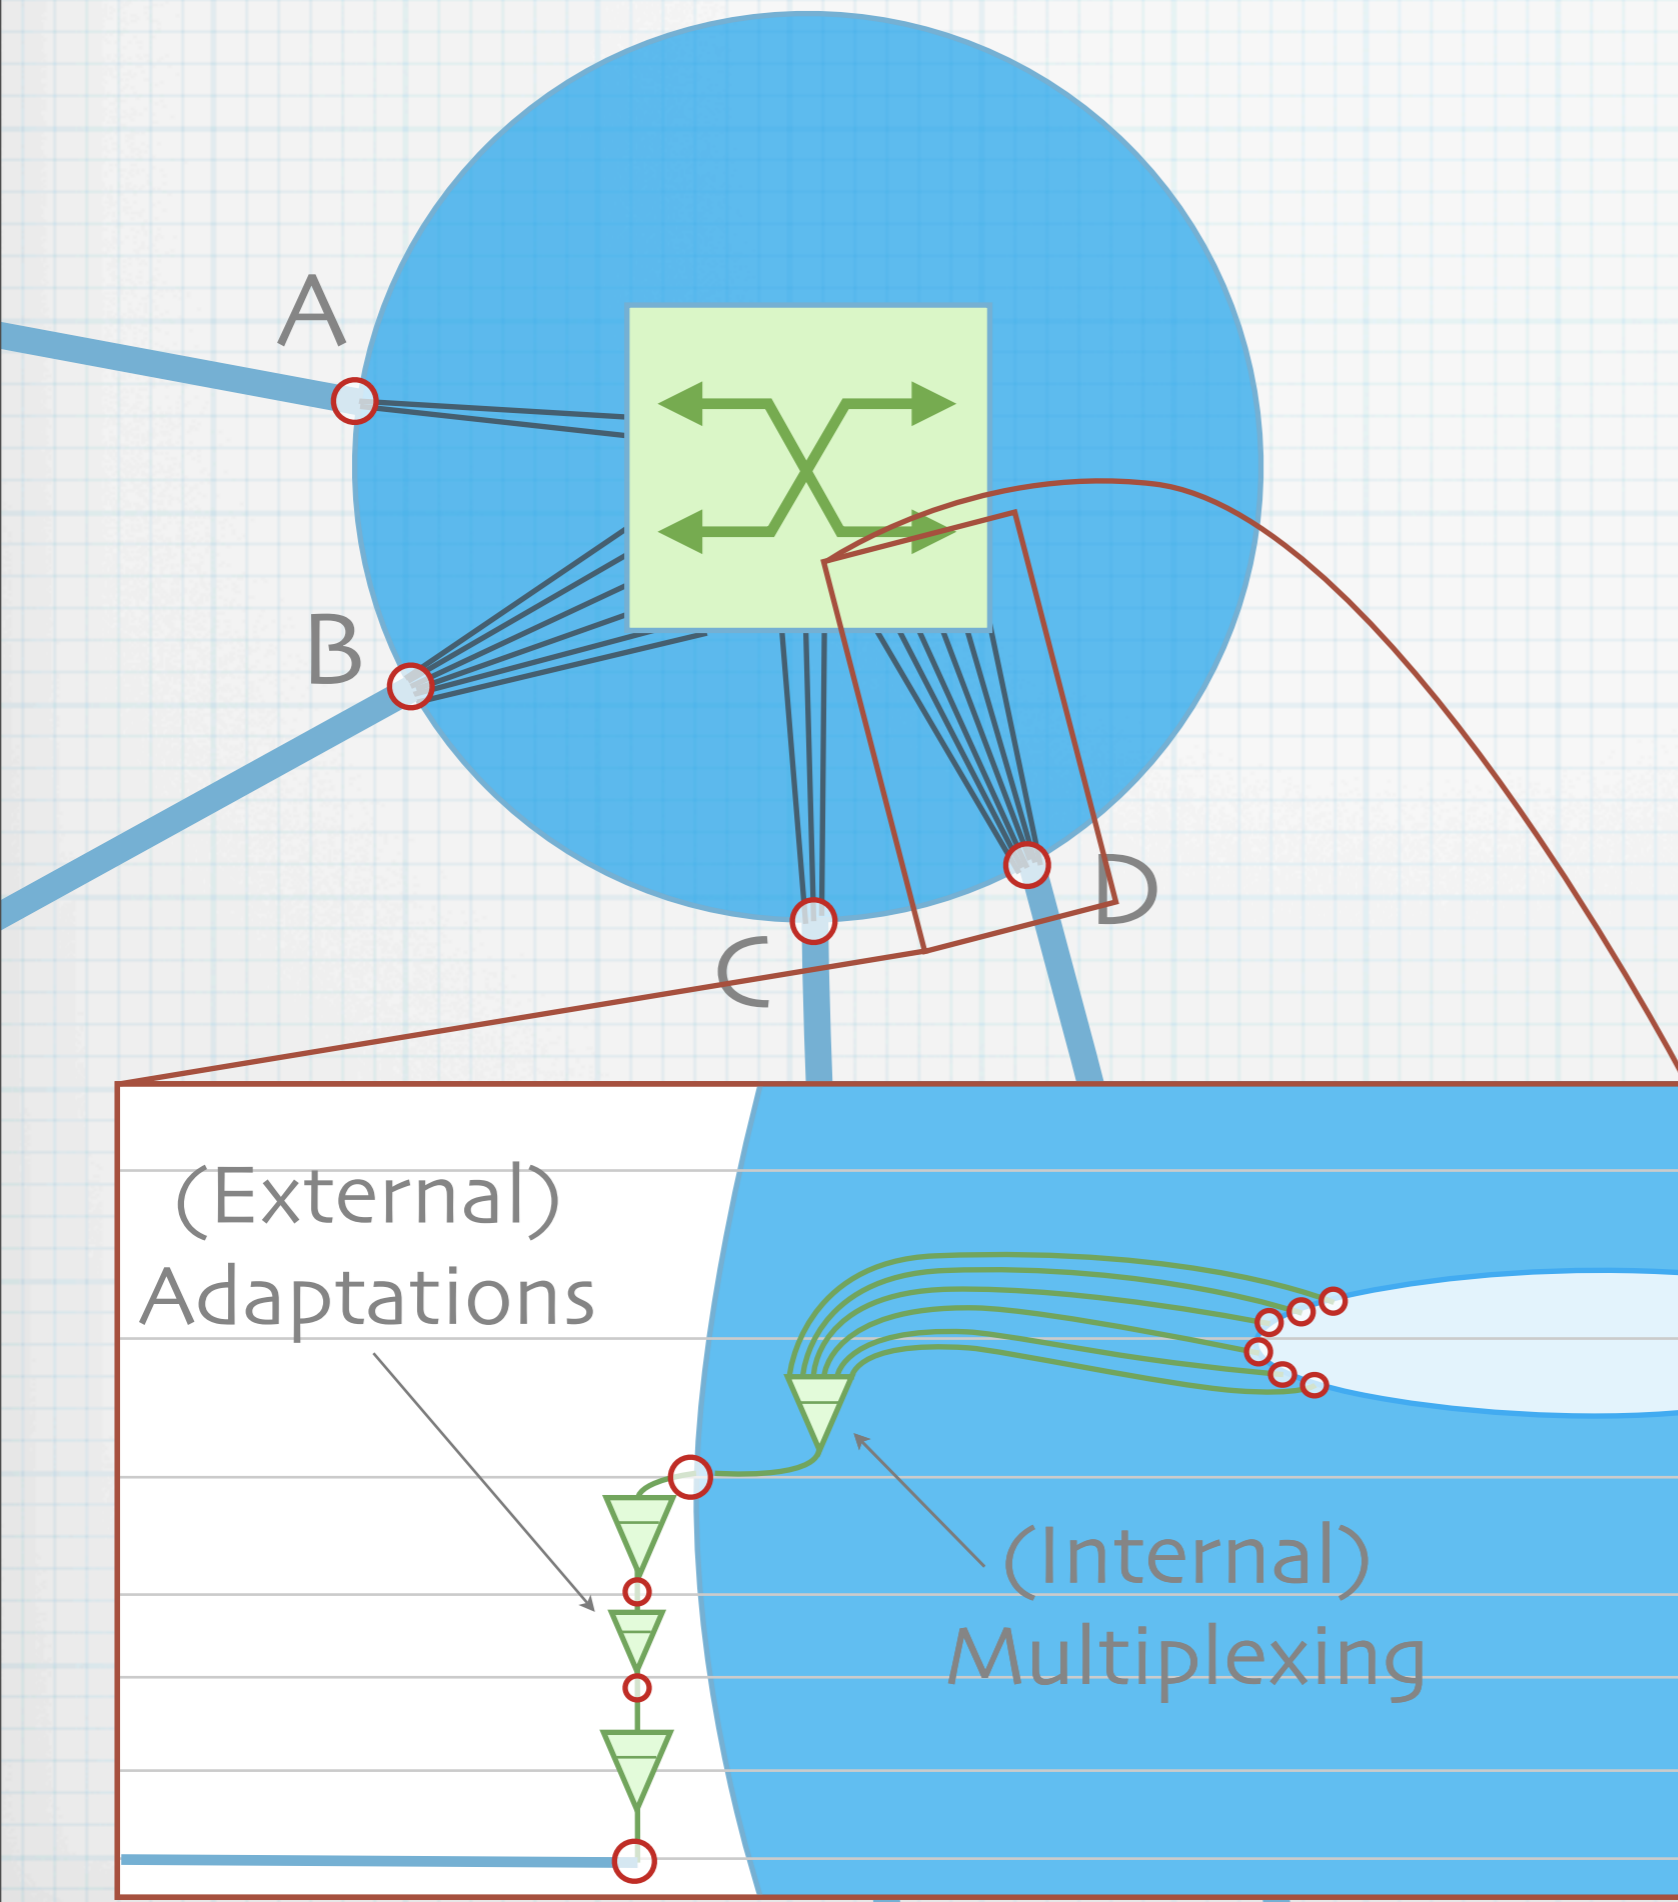

Channel Identifier

switchedTo → **Interface**

A subnetwork connection

Interfaces:

- A. Ethernet interface (over UTP) (Adapts in STS-3c-7v)
- B. OC-192 interface
- C. OC-48 interface (over fiber)
- D. OC-192 interface (over DWDM at 1552.52nm over fiber)

Ethernet layer

STS layer

Optical Carrier layer

Lambda layer

DWDM layer

UTP layer

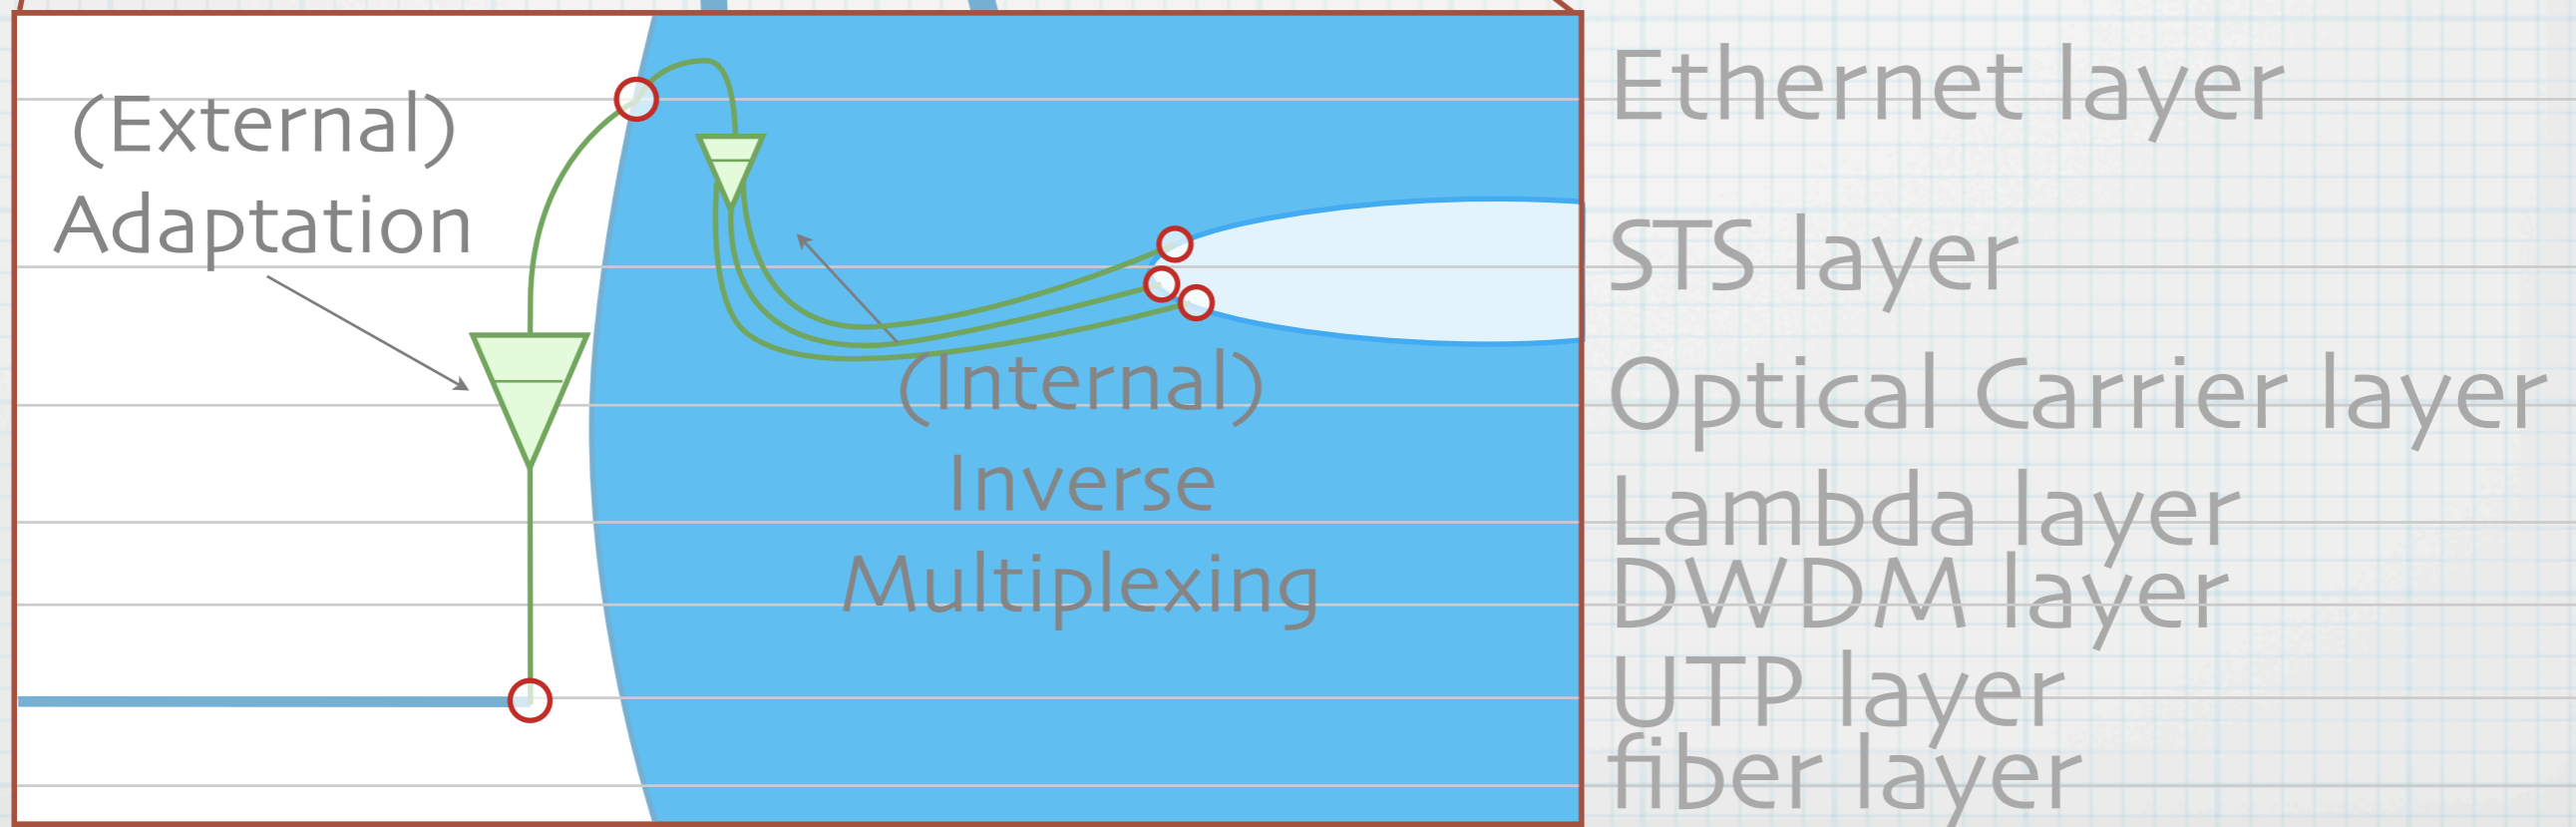

fiber layer

(External)
Adaptations

(Internal)
Multiplexing

Interfaces:

- A. Ethernet interface (over UTP) (Adapts in STS-3c-7v)
- B. OC-192 interface
- C. OC-48 interface (over fiber)
- D. OC-192 interface (over DWDM at 1552.52nm over fiber)

dinsdag 18 september 2007

Examples of mapping interface -> functional elements (connection points and adaptation functions)

Adaptation

Multiplexing
Adaptation

Inverse
Multiplexing
Adaptation

Adaptation

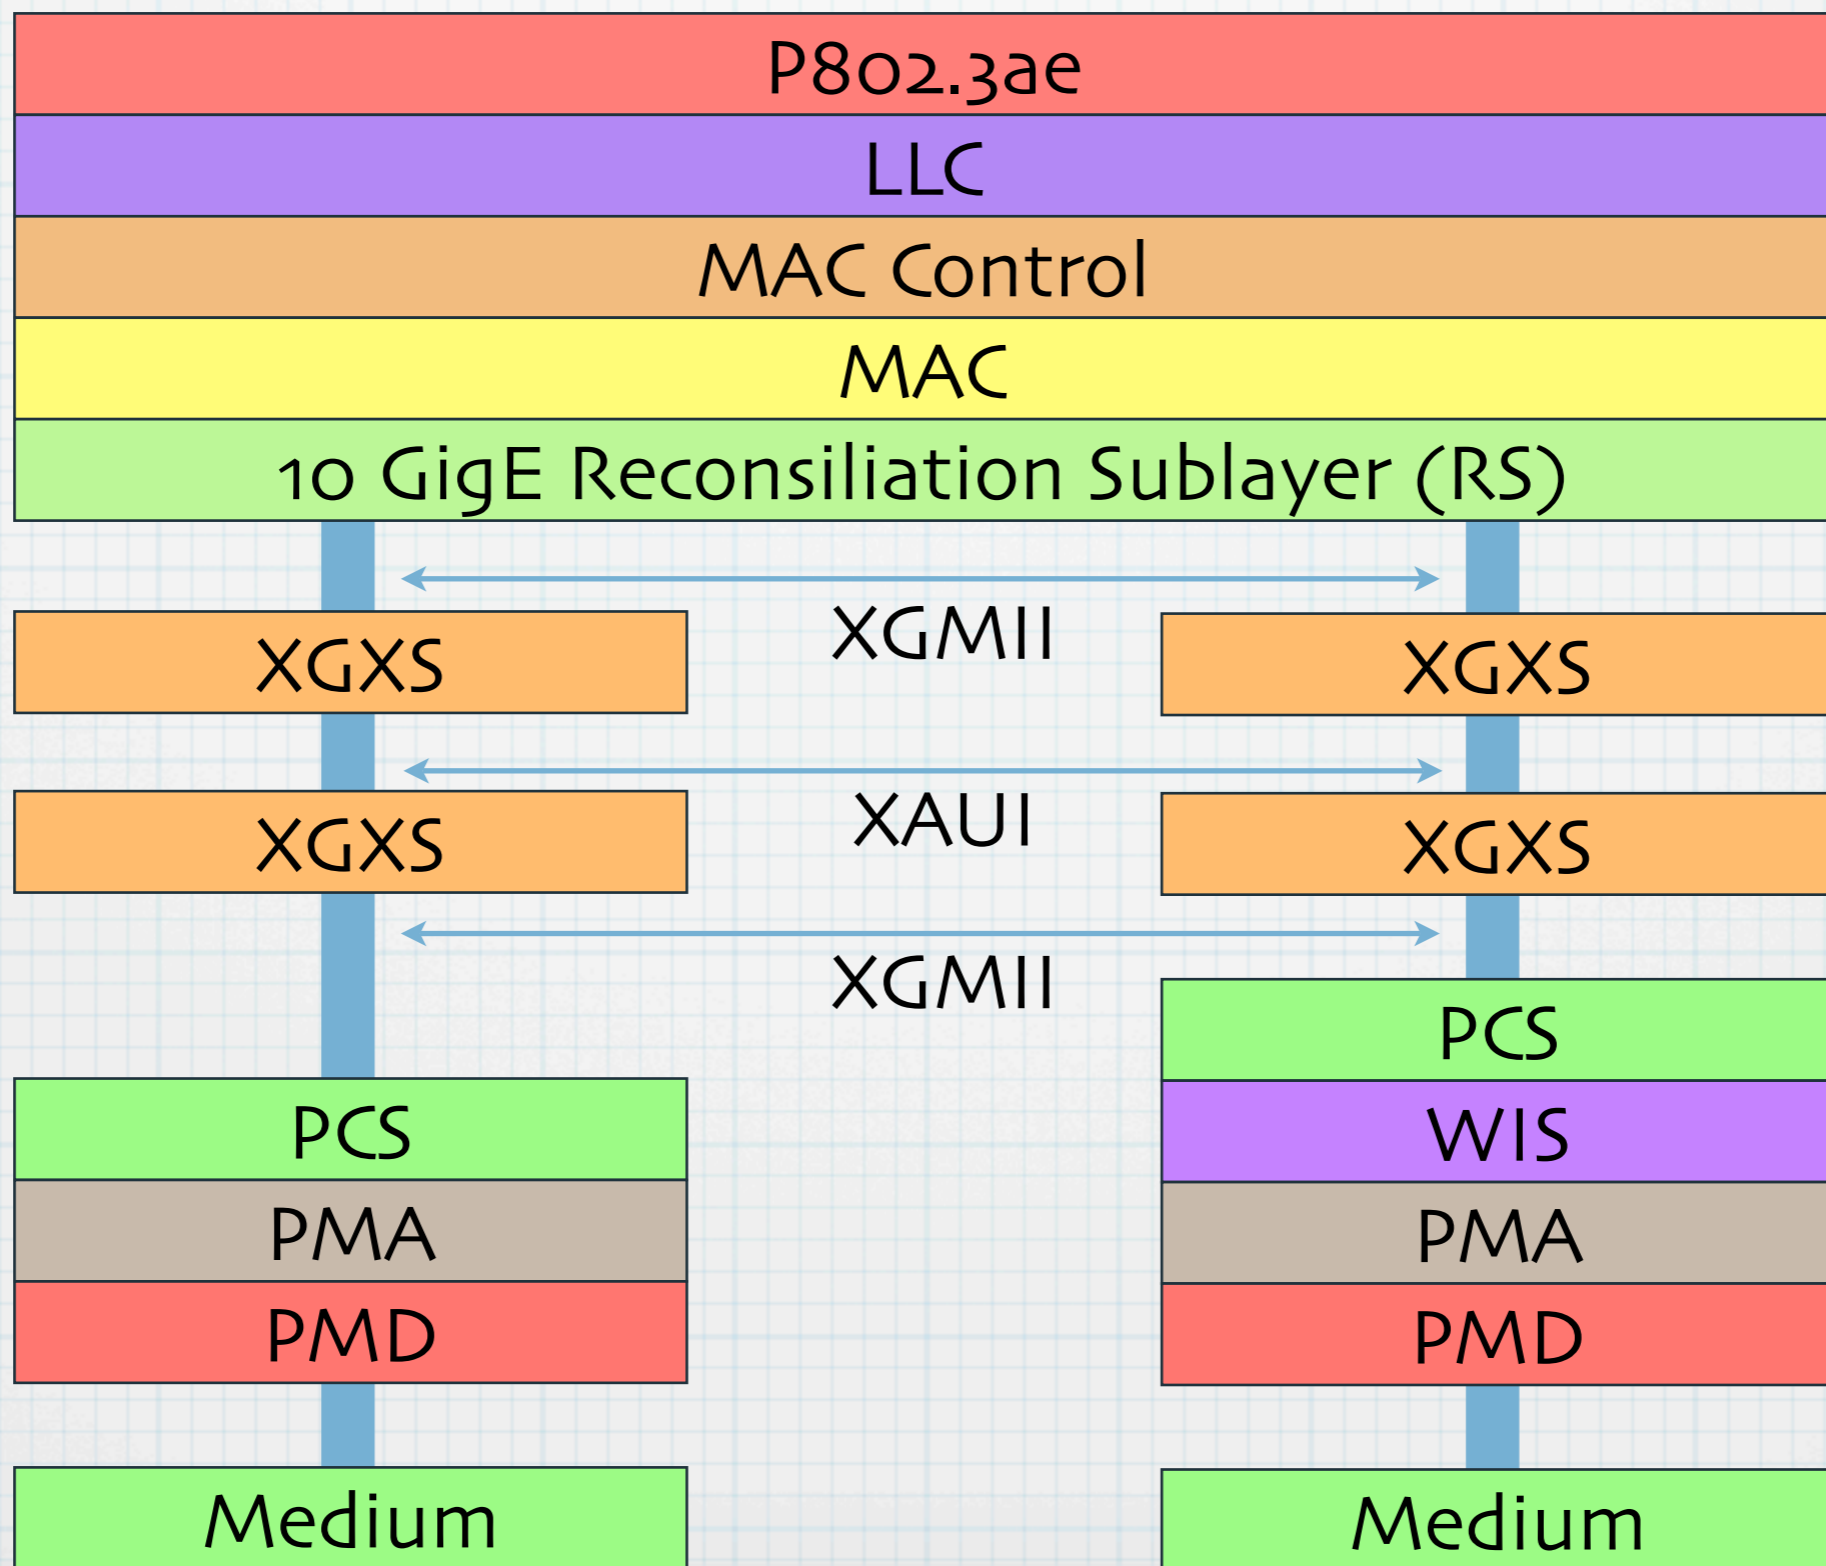

rdf:ID	→ URI
clientLayer	→ Layer
serverLayer	→ Layer
labels	→ LabelSet
	allowed/available labels
clientLayerCount	→ integer
	>1 for multiplexing.
serverLayerCount	→ integer
	1 by default.
	>1 for inverse multiplexing.
clientCapacity	→ float
	provided max. capacity in Bytes/s to the client layer.
serverCapacity	→ float
	required min. capacity in Bytes/s per channel from the client layer.
serverPropertyValues	→ PropertyValues

Example of adaptation: Ethernet over UTP, or Ethernet over Fiber.

Example of multiplexing: different data streams, each in a separate wavelength.

Example of inverse multiplexing: Ethernet in multiple STS timeslots.

Technology Specific Schemas

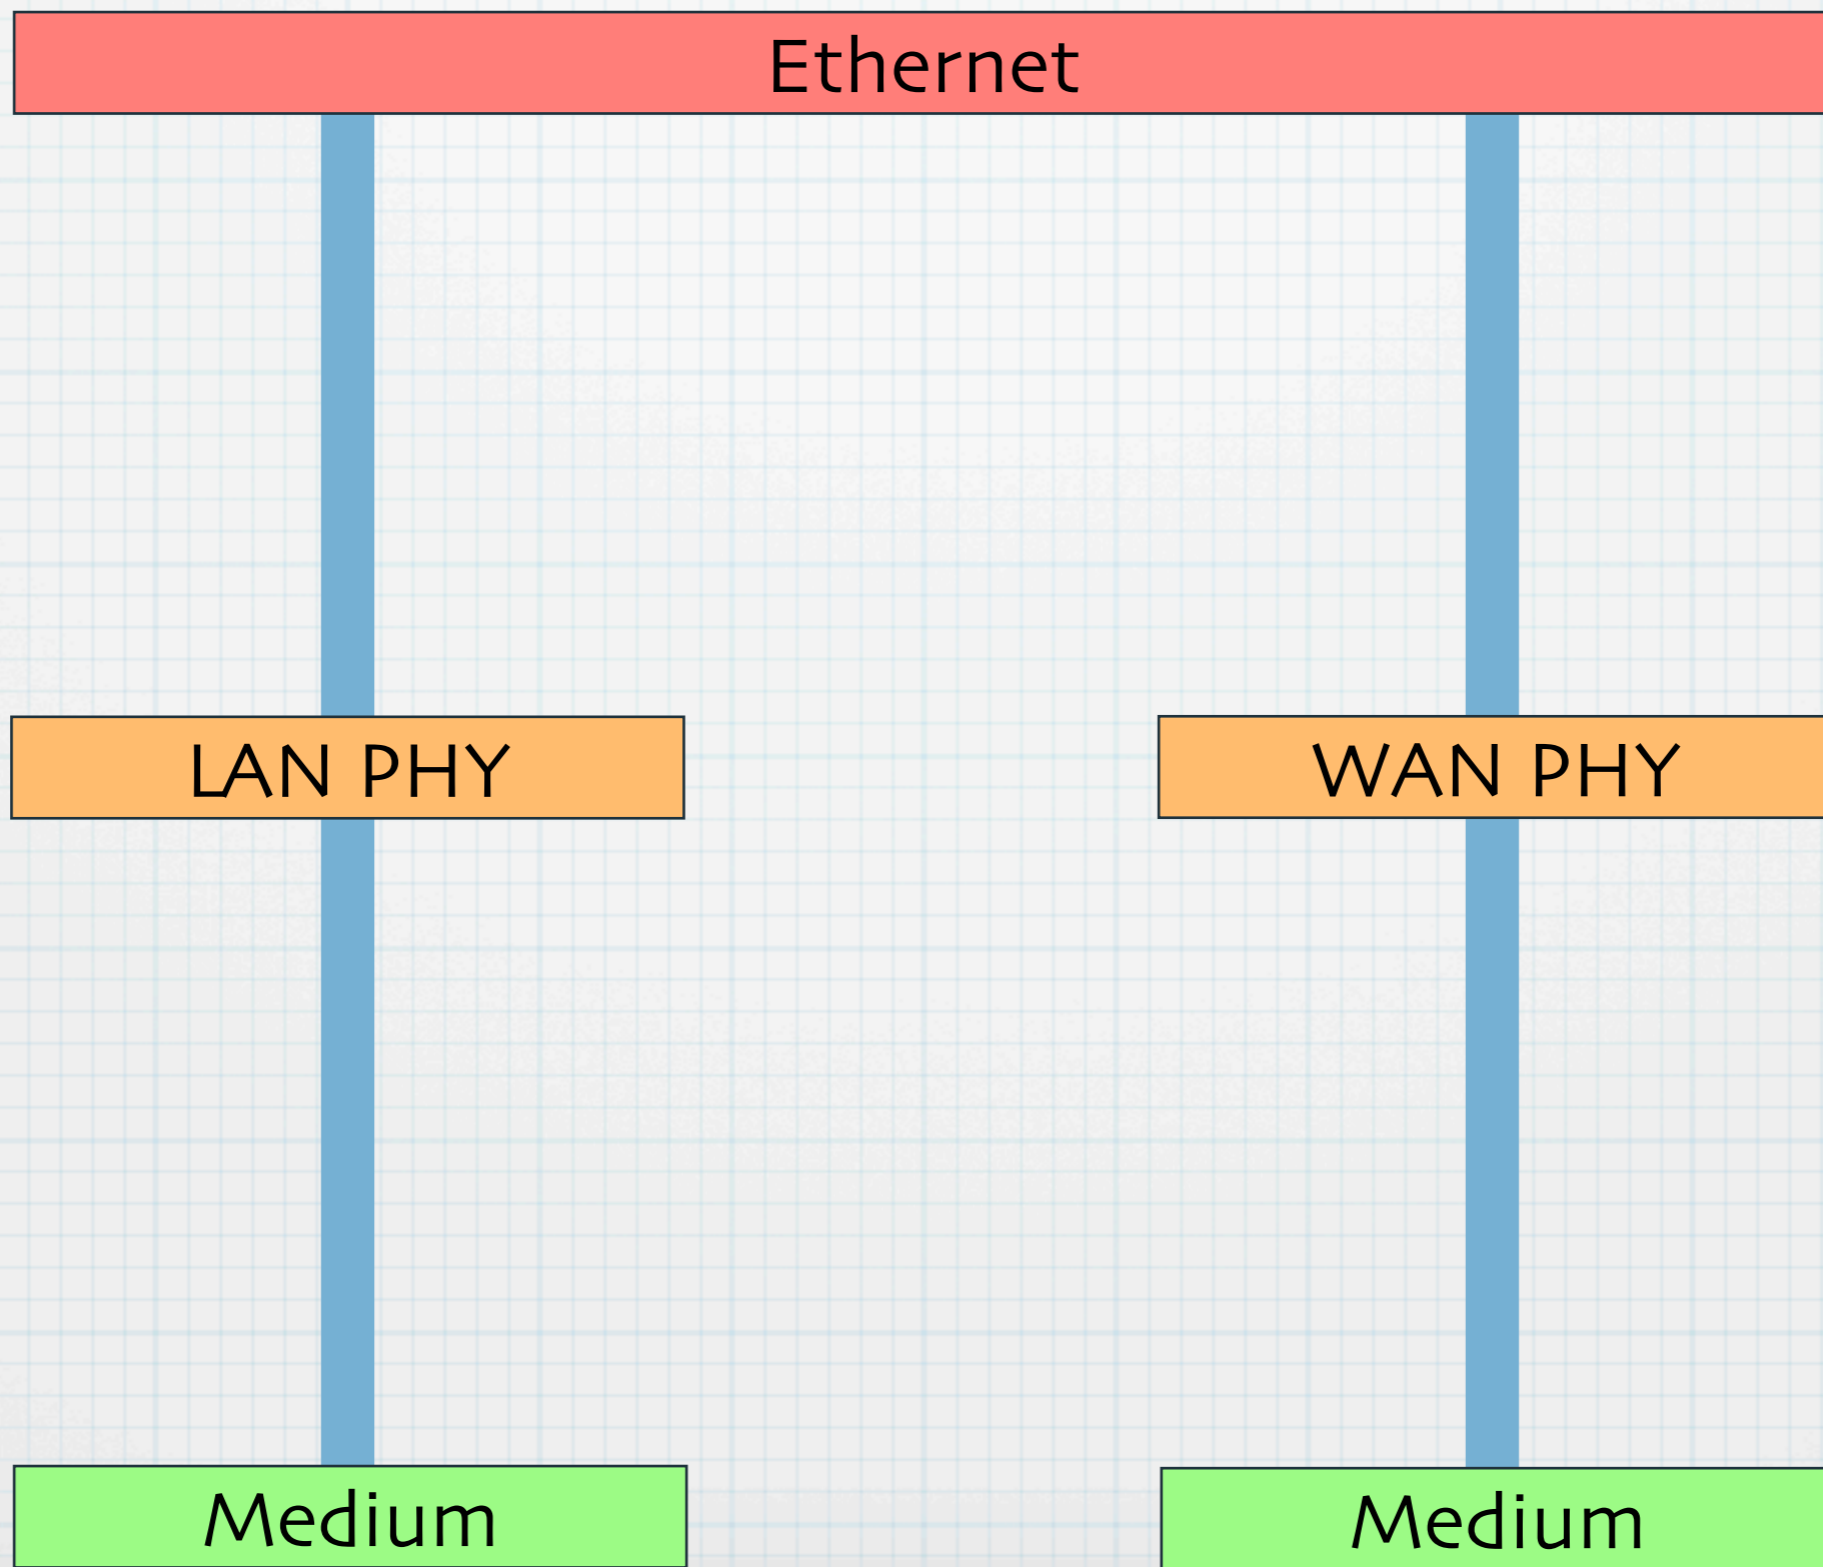

Data link layer only

dinsdag 18 september 2007

Reason to separate technology schemas from other schemas: we want to allow changes to the schema.

It is not clear how much simplification we allow in the schema. Here is an example of a model with lots of details. Left: LAN PHY, Right: WAN PHY Ethernet

Technology Specific Schemas

Data link layer only

dinsdag 18 september 2007

More simple description of same layers.

Reason to for me describe networks: describe incompatibilities for path finding, so I don't need more info. Perhaps someone else may.

Create a **computer-readable network description**, that provides enough **information for path finding in multi-layer networks**.

We don't want path finding to have knowledge of each and every possible adaptation.

Let's make the path finding layer-agnostic, by describing layers and technologies in RDF as well.

Different Subtopics

- Topology
(existing NDL schema)
- Layer specification
Definition of different Layers
Layer, LabelType, Adaptation
- Device capabilities
Configurable Interfaces,
switching & swapping capability.
- Device configuration
Internal connections, available
labels (e.g. free VC-4 channels)
- Domain abstraction ...
- Path Requests ...

- IP schema
- Ethernet schema
- ATM schema
- SONET/SDH
schema
- WDM schema
- Physical layer
schema
- Fiber bundle
schema

dinsdag 18 september 2007

Each subtopic got it's own schema. We have 4 basic schemas (not mentioned: physical properties, re-use CIM).

In addition, we have 6 layer-specific schema.

Capability: needed for path finding; Configuration: needed for fault isolation.

Network Description

Technology Description

```

Every domain publishes its own data. RDF allows domains to link to each other. Publication can be (semi-)static, or using webservice.

Python NDL Toolkit

- Input of network and technology descriptions in NDL/RDF
- Partial RDF schema parser
- Input of network descriptions from devices (TL1, CLI or OSPF)
- TL1, CLI, OSPF parsers
(Similar to SARA Perl TL1 toolkit, only in Python)
- Output to NDL/RDF
- Output to DOT (Graphviz)
- Path Walk (existing connections)
- Path Find (available connections)

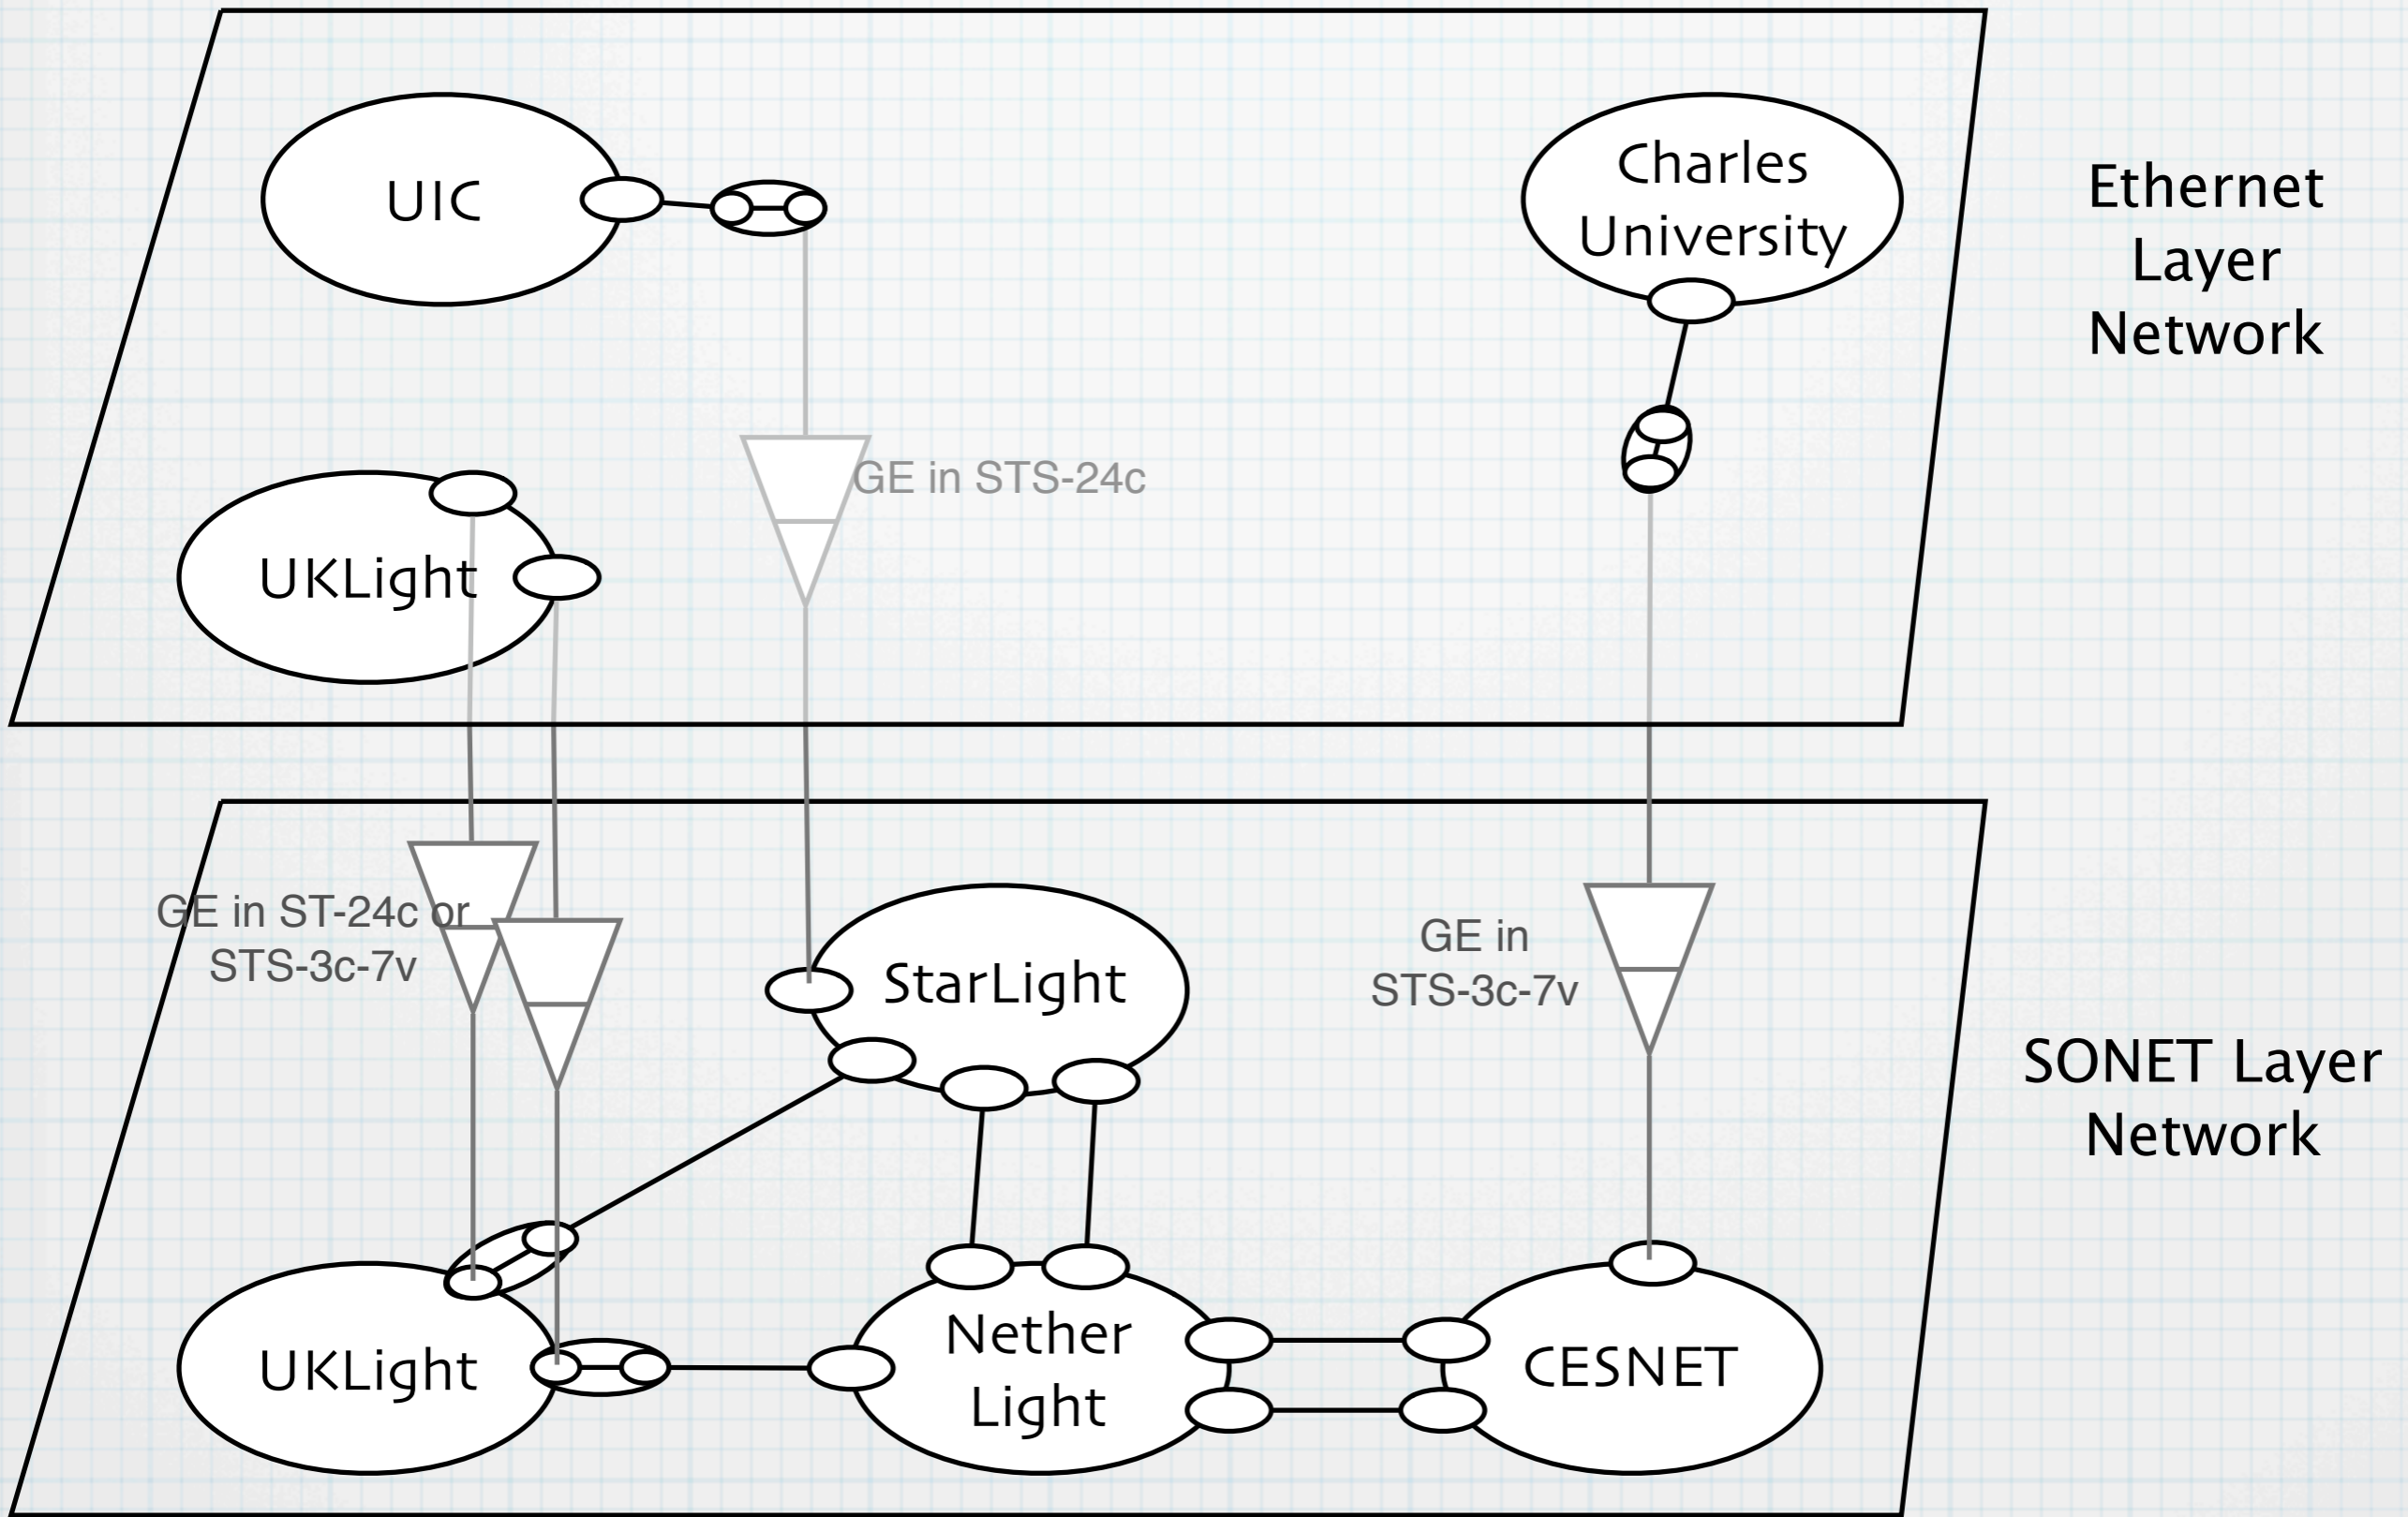

dinsdag 18 september 2007

Now we can make network descriptions. (Step 2 is done).
Next up, step 3: Make software to do something useful with it.
Available for download. (BSD-license)

dinsdag 18 september 2007

This is our network. It's an example based on a practical problem in the GLIF about 2004. Hybrid: different technologies/layers. Different adaptations between layers. Not all available. Question for the network engineers in the audience: please find the shortest working path from University of Illinois at Chicago to Charles University in Prague.

Path Finding

Demo & Papers

See downstairs or

<http://ndl.uva.netherlight.nl/>

Basics Concepts

- Adaptation stacks
- Switch matrix
- Switching and swapping
- Labels
- Multiplexing (potential interfaces)

The Schema

Advanced Concepts

- Optional vs. compulsory labels
- Ingress/egress label (packet switching)
- Internal labels (Untagged Ethernet)
- Internal adaptation stack
- Inverse multiplexing (> 1 server layer)
- Multicast switching
- Broadcast switching

The Schema

Interfaces

- **Static Interface**

Fixed interface. Can not be changed in any way.

laser at 1310 nm

- **Configurable Interface**

Interface always exists, but can still be configured.

tunable laser

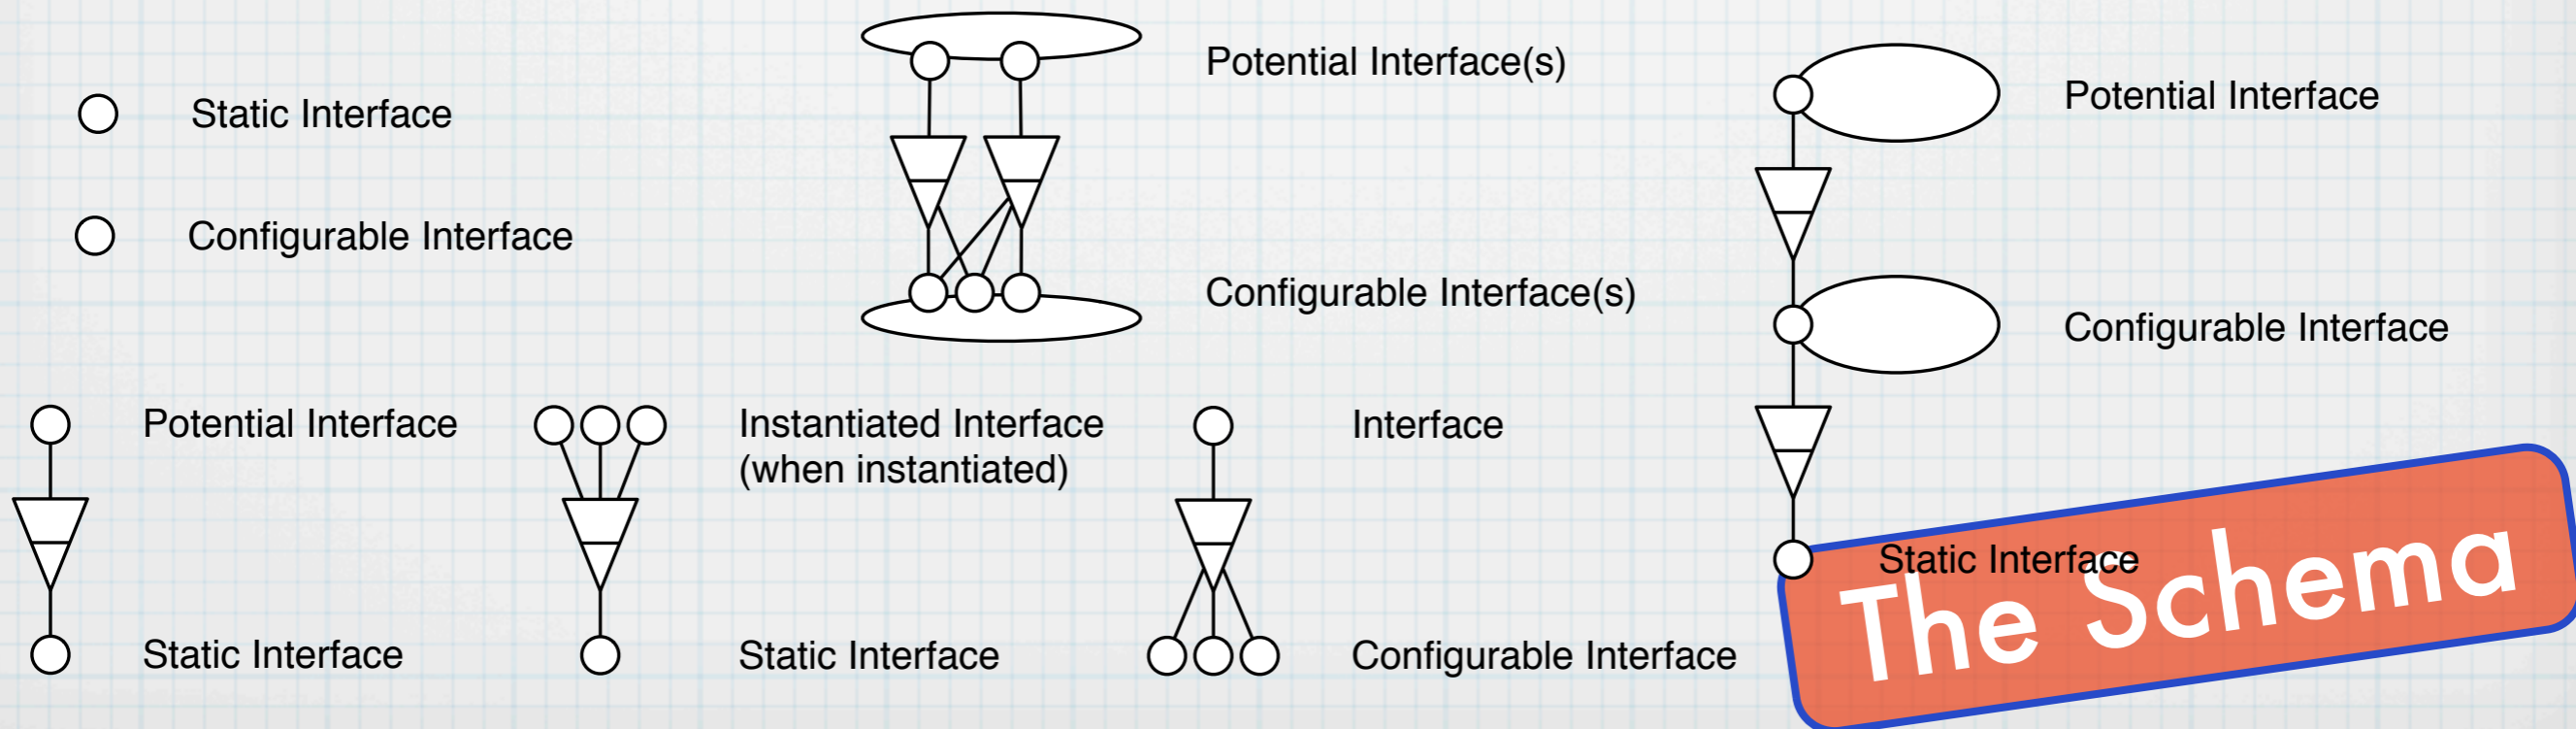

- **Potential Interface**

Abstract interface. 0, 1 or many of these interface can be configured.

"It is possible to create Tagged Ethernet channels"

- **Instantiated Interface**

Instantiation of a Potential Interface. Configured timeslot on VC-4 layer.

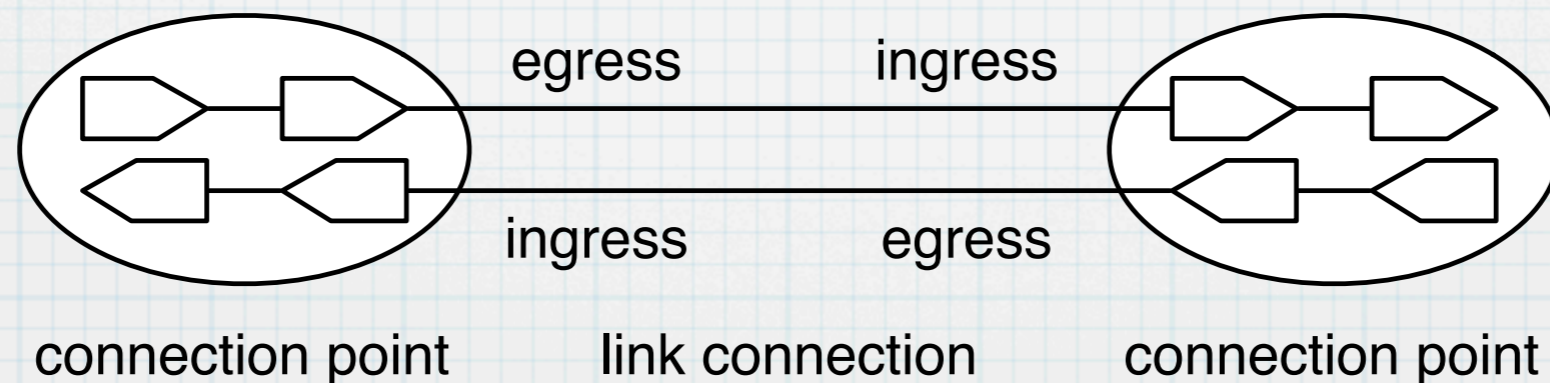

Semantic Challenges

X linkTo Y, but not Y linkTo X means:

- a unidirectional link
- only X is configured, Y is not (but X would accept data from Y).

Which of the connection points below is configured (admin up/link up), and is there a fiber?

Challenges

Semantic Challenges

What does a **Potential** or **Available** configuration mean:

- Is it technically possible? Possible without breaking other connections ?
If so, what does “breaking” mean? What if I reconfigure the other switch connection? Is that broken?
- Is it administratively possible?

We distinguish between actual (is configured/static), potential and available

Challenges

Semantic Challenges

If a layer has a label, does it have to exist for an actual Interface?

- The Ethernet label is the VLAN (IEEE 802.1Q) label.
- It is only embedded in the data itself for Ethernet over Ethernet (Tagged Ethernet).
- For untagged Ethernet, it is used for switching within a switch matrix
- An untagged channel can have different “label” at each end.

Our solution: we use the “empty label” as concept, but still sometimes it **MUST** be empty, sometimes it **MUST NOT** be empty

We only use the IEEE 802.1Q label as the actual label (in the GMPLS sense), and the VLAN tag as an “internal label”, for switching only.

Challenges

Logical Challenges

Give me all “switchTo” means:

Depends on:

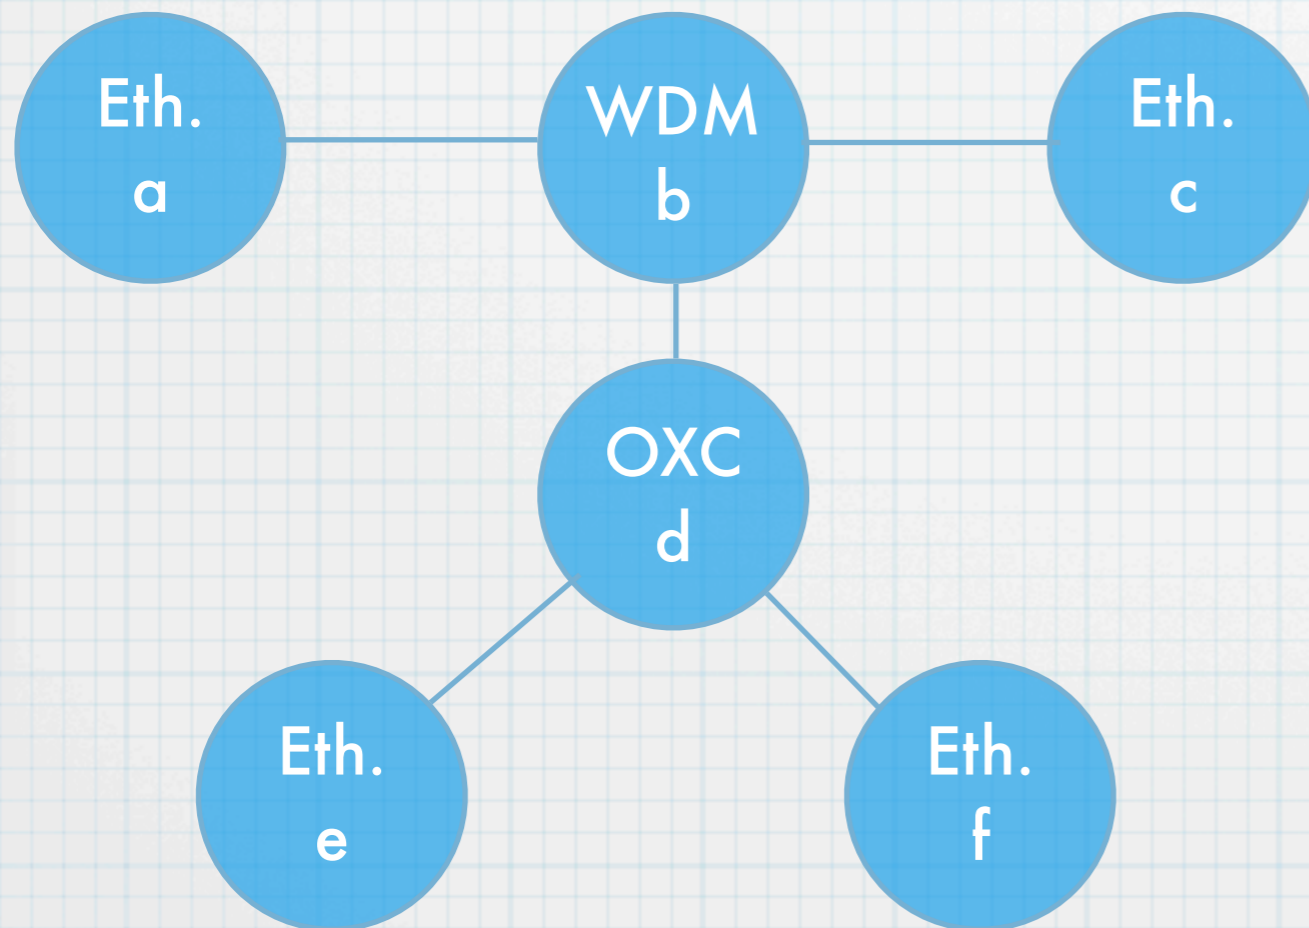

- Question: do you want Actual/Potential/Available switchTo?
- What kind of interfaces are we talking about: Static/Configurable/Potential/Instantiated
Do we return one or two switchTo for a Potential and Instantiated interface?
- What type of switch matrix, if any: None (patch panel)/Unicast/Multicast/Broadcast
- Can the switch matrix convert between labels (switching & swapping)

Challenges

Logical Challenges

When is a switchTo (subnetwork connection) in use?

- We can re-use a connection at a lower layer, as long as the labels are different on higher layers (different channels).

Example:

Ethernet A -> C need to go to E and F:

- A -> E: 10 Gb/s LAN PHY
- E -> F: 10 Gb/s WAN PHY
- F -> C: 1 Gb/s

How/when to detect that this is not possible due to a conflict at OXC d?

Challenges

Logical Challenges

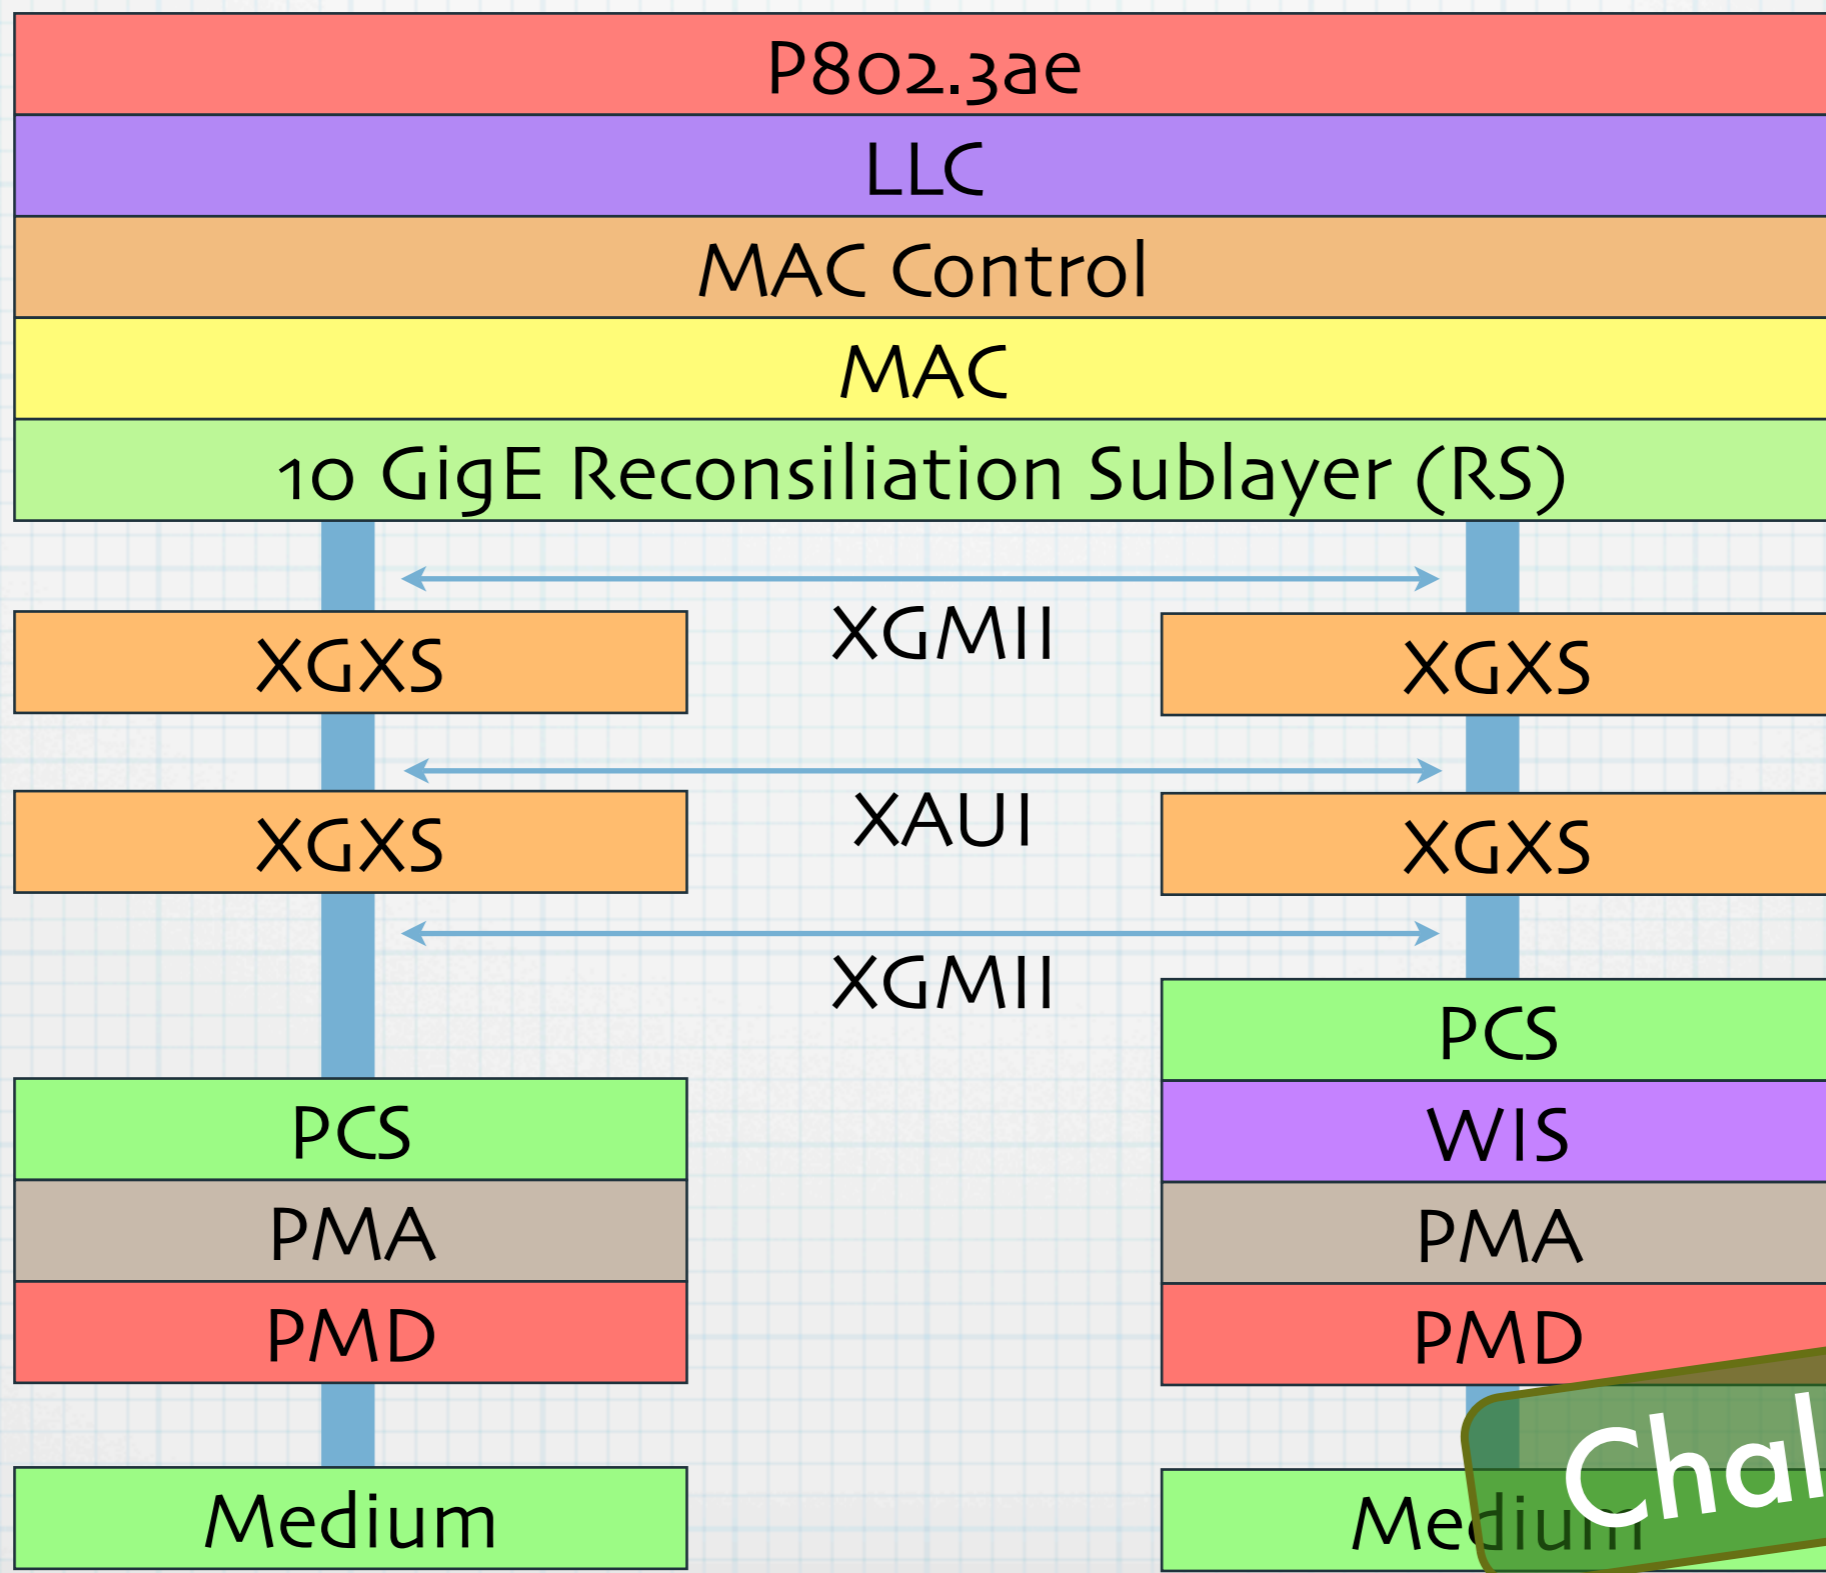

For a path, 4 channels over the same client layer are required:

- A. Must have label in set {3,4}
- B. Must have label in set {3,4}
- C. Must have label in set {3}
- D. Must have label in set {4-11}

How to detect this is not possible? If we sequentially pick a label for each channel, we may get a false negative.

Challenges

Practical Challenges

Thank You
